

Errors and Exceptions

Until now error messages haven't been more than mentioned, but if you have tried out the examples you have probably seen some. There are (at least) two distinguishable kinds of errors: *syntax errors* and *exceptions*.

Syntax Errors

Syntax errors, also known as parsing errors, are perhaps the most common kind of complaint you get while you are still learning Python:

```
>>> while True: print('Hello world')
      File "<stdin>", line 1
        while True: print('Hello world')
                        ^
SyntaxError: invalid syntax
```

The parser repeats the offending line and displays a little 'arrow' pointing at the earliest point in the line where the error was detected. The error is caused by (or at least detected at) the token *preceding* the arrow: in the example, the error is detected at the function `:func: print`, since a colon (':') is missing before it. File name and line number are printed so you know where to look in case the input came from a script.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 26); [backlink](#)

Unknown interpreted text role "func".

Exceptions

Even if a statement or expression is syntactically correct, it may cause an error when an attempt is made to execute it. Errors detected during execution are called *exceptions* and are not unconditionally fatal: you will soon learn how to handle them in Python programs. Most exceptions are not handled by programs, however, and result in error messages as shown here:

```
>>> 10 * (1/0)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ZeroDivisionError: division by zero
>>> 4 + spam*3
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
NameError: name 'spam' is not defined
>>> '2' + 2
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: can only concatenate str (not "int") to str
```

The last line of the error message indicates what happened. Exceptions come in different types, and the type is printed as part of the message: the types in the example are `:exc:ZeroDivisionError`, `:exc:NameError` and `:exc:TypeError`. The string printed as the exception type is the name of the built-in exception that occurred. This is true for all built-in exceptions, but need not be true for user-defined exceptions (although it is a useful convention). Standard exception names are built-in identifiers (not reserved keywords).

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 58); [backlink](#)

Unknown interpreted text role "exc".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 58); [backlink](#)

Unknown interpreted text role "exc".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 58); [backlink](#)

Unknown interpreted text role "exc".

The rest of the line provides detail based on the type of exception and what caused it.

The preceding part of the error message shows the context where the exception occurred, in the form of a stack traceback. In

general it contains a stack traceback listing source lines; however, it will not display lines read from standard input.

`ref:'builtin-exceptions'` lists the built-in exceptions and their meanings.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 74); [backlink](#)

Unknown interpreted text role "ref".

Handling Exceptions

It is possible to write programs that handle selected exceptions. Look at the following example, which asks the user for input until a valid integer has been entered, but allows the user to interrupt the program (using `kbd:'Control-C'` or whatever the operating system supports); note that a user-generated interruption is signalled by raising the `exc:'KeyboardInterrupt'` exception.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 82); [backlink](#)

Unknown interpreted text role "kbd".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 82); [backlink](#)

Unknown interpreted text role "exc".

```
>>> while True:
...     try:
...         x = int(input("Please enter a number: "))
...         break
...     except ValueError:
...         print("Oops! That was no valid number. Try again...")
... 
```

The `keyword:'try'` statement works as follows.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 96); [backlink](#)

Unknown interpreted text role "keyword".

- First, the *try clause* (the statement(s) between the `keyword:'try'` and `keyword:'except'` keywords) is executed.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 98); [backlink](#)

Unknown interpreted text role "keyword".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 98); [backlink](#)

Unknown interpreted text role "keyword".

- If no exception occurs, the *except clause* is skipped and execution of the `keyword:'try'` statement is finished.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 101); [backlink](#)

Unknown interpreted text role "keyword".

- If an exception occurs during execution of the `keyword:'try'` clause, the rest of the clause is skipped. Then, if its type matches the exception named after the `keyword:'except'` keyword, the *except clause* is executed, and then execution continues after the try/except block.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-

resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 104); [backlink](#)

Unknown interpreted text role "keyword".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 104); [backlink](#)

Unknown interpreted text role "keyword".

- If an exception occurs which does not match the exception named in the *except clause*, it is passed on to outer `:keyword:'try'` statements; if no handler is found, it is an *unhandled exception* and execution stops with a message as shown above.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 109); [backlink](#)

Unknown interpreted text role "keyword".

A `:keyword:'try'` statement may have more than one *except clause*, to specify handlers for different exceptions. At most one handler will be executed. Handlers only handle exceptions that occur in the corresponding *try clause*, not in other handlers of the same `:keyword:'!try'` statement. An *except clause* may name multiple exceptions as a parenthesized tuple, for example:

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 114); [backlink](#)

Unknown interpreted text role "keyword".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 114); [backlink](#)

Unknown interpreted text role "keyword".

```
... except (RuntimeError, TypeError, NameError):  
...     pass
```

A class in an `:keyword:'except'` clause is compatible with an exception if it is the same class or a base class thereof (but not the other way around --- an *except clause* listing a derived class is not compatible with a base class). For example, the following code will print B, C, D in that order:

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 123); [backlink](#)

Unknown interpreted text role "keyword".

```
class B(Exception):  
    pass  
  
class C(B):  
    pass  
  
class D(C):  
    pass  
  
for cls in [B, C, D]:  
    try:  
        raise cls()  
    except D:  
        print("D")  
    except C:  
        print("C")  
    except B:  
        print("B")
```

Note that if the *except clauses* were reversed (with `except B` first), it would have printed B, B, B --- the first matching *except clause* is triggered.

All exceptions inherit from `:exc:'BaseException'`, and so it can be used to serve as a wildcard. Use this with extreme caution, since it is easy to mask a real programming error in this way! It can also be used to print an error message and then re-raise the exception (allowing a caller to handle the exception as well):

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 150); [backlink](#)

Unknown interpreted text role "exc".

```
import sys

try:
    f = open('myfile.txt')
    s = f.readline()
    i = int(s.strip())
except OSError as err:
    print("OS error: {0}".format(err))
except ValueError:
    print("Could not convert data to an integer.")
except BaseException as err:
    print(f"Unexpected {err=}, {type(err)=}")
    raise
```

Alternatively the last except clause may omit the exception name(s), however the exception value must then be retrieved with `sys.exception()`.

The **keyword:**`'try'` ... **keyword:**`'except'` statement has an optional *else clause*, which, when present, must follow all *except clauses*. It is useful for code that must be executed if the *try clause* does not raise an exception. For example:

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 172); [backlink](#)

Unknown interpreted text role "keyword".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 172); [backlink](#)

Unknown interpreted text role "keyword".

```
for arg in sys.argv[1:]:
    try:
        f = open(arg, 'r')
    except OSError:
        print('cannot open', arg)
    else:
        print(arg, 'has', len(f.readlines()), 'lines')
        f.close()
```

The use of the **keyword:**`'else'` clause is better than adding additional code to the **keyword:**`'try'` clause because it avoids accidentally catching an exception that wasn't raised by the code being protected by the **keyword:**`'!try'` ... **keyword:**`'!except'` statement.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 186); [backlink](#)

Unknown interpreted text role "keyword".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 186); [backlink](#)

Unknown interpreted text role "keyword".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 186); [backlink](#)

Unknown interpreted text role "keyword".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 186); [backlink](#)

Unknown interpreted text role "keyword".

When an exception occurs, it may have an associated value, also known as the exception's *argument*. The presence and type of the argument depend on the exception type.

The *except clause* may specify a variable after the exception name. The variable is bound to an exception instance with the

arguments stored in `instance.args`. For convenience, the exception instance defines `meth: '__str__'` so the arguments can be printed directly without having to reference `.args`. One may also instantiate an exception first before raising it and add any attributes to it as desired.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 195); [backlink](#)

Unknown interpreted text role "meth".

```
>>> try:
...     raise Exception('spam', 'eggs')
... except Exception as inst:
...     print(type(inst))    # the exception instance
...     print(inst.args)    # arguments stored in .args
...     print(inst)         # __str__ allows args to be printed directly,
...                         # but may be overridden in exception subclasses
...     x, y = inst.args    # unpack args
...     print('x =', x)
...     print('y =', y)
...
<class 'Exception'>
('spam', 'eggs')
('spam', 'eggs')
x = spam
y = eggs
```

If an exception has arguments, they are printed as the last part ('detail') of the message for unhandled exceptions.

Exception handlers don't just handle exceptions if they occur immediately in the *try clause*, but also if they occur inside functions that are called (even indirectly) in the *try clause*. For example:

```
>>> def this_fails():
...     x = 1/0
...
>>> try:
...     this_fails()
... except ZeroDivisionError as err:
...     print('Handling run-time error:', err)
...
Handling run-time error: division by zero
```

Raising Exceptions

The `keyword: 'raise'` statement allows the programmer to force a specified exception to occur. For example:

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 242); [backlink](#)

Unknown interpreted text role "keyword".

```
>>> raise NameError('HiThere')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
NameError: HiThere
```

The sole argument to `keyword: 'raise'` indicates the exception to be raised. This must be either an exception instance or an exception class (a class that derives from `class: 'Exception'`). If an exception class is passed, it will be implicitly instantiated by calling its constructor with no arguments:

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 250); [backlink](#)

Unknown interpreted text role "keyword".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 250); [backlink](#)

Unknown interpreted text role "class".

```
raise ValueError # shorthand for 'raise ValueError()'
```

If you need to determine whether an exception was raised but don't intend to handle it, a simpler form of the `keyword: 'raise'` statement allows you to re-raise the exception:

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 257); [backlink](#)

Unknown interpreted text role "keyword".

```
>>> try:
...     raise NameError('HiThere')
... except NameError:
...     print('An exception flew by!')
...     raise
...
An exception flew by!
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
NameError: HiThere
```

Exception Chaining

The `keyword:raise` statement allows an optional `keyword:from<raise>` which enables chaining exceptions. For example:

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 278); [backlink](#)

Unknown interpreted text role "keyword".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 278); [backlink](#)

Unknown interpreted text role "keyword".

```
# exc must be exception instance or None.
raise RuntimeError from exc
```

This can be useful when you are transforming exceptions. For example:

```
>>> def func():
...     raise ConnectionError
...
>>> try:
...     func()
... except ConnectionError as exc:
...     raise RuntimeError('Failed to open database') from exc
...
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
  File "<stdin>", line 2, in func
ConnectionError
<BLANKLINE>
The above exception was the direct cause of the following exception:
<BLANKLINE>
Traceback (most recent call last):
  File "<stdin>", line 4, in <module>
RuntimeError: Failed to open database
```

Exception chaining happens automatically when an exception is raised inside an `keyword:except` or `keyword:finally` section. This can be disabled by using `from None` idiom:

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 305); [backlink](#)

Unknown interpreted text role "keyword".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 305); [backlink](#)

Unknown interpreted text role "keyword".

```
>>> try:
...     open('database.sqlite')
... except OSError:
...     raise RuntimeError from None
...
Traceback (most recent call last):
```

```
File "<stdin>", line 4, in <module>
RuntimeError
```

For more information about chaining mechanics, see [ref: builtin-exceptions](#).

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 318); [backlink](#)

Unknown interpreted text role "ref".

User-defined Exceptions

Programs may name their own exceptions by creating a new exception class (see [ref: tut-classes](#) for more about Python classes). Exceptions should typically be derived from the `exc:Exception` class, either directly or indirectly.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 326); [backlink](#)

Unknown interpreted text role "ref".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 326); [backlink](#)

Unknown interpreted text role "exc".

Exception classes can be defined which do anything any other class can do, but are usually kept simple, often only offering a number of attributes that allow information about the error to be extracted by handlers for the exception.

Most exceptions are defined with names that end in "Error", similar to the naming of the standard exceptions.

Many standard modules define their own exceptions to report errors that may occur in functions they define. More information on classes is presented in chapter [ref: tut-classes](#).

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 337); [backlink](#)

Unknown interpreted text role "ref".

Defining Clean-up Actions

The `keyword:try` statement has another optional clause which is intended to define clean-up actions that must be executed under all circumstances. For example:

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 347); [backlink](#)

Unknown interpreted text role "keyword".

```
>>> try:
...     raise KeyboardInterrupt
... finally:
...     print('Goodbye, world!')
...
Goodbye, world!
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
KeyboardInterrupt
```

If a `keyword:finally` clause is present, the `keyword:!finally` clause will execute as the last task before the `keyword:try` statement completes. The `keyword:!finally` clause runs whether or not the `keyword:!try` statement produces an exception. The following points discuss more complex cases when an exception occurs:

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 361); [backlink](#)

Unknown interpreted text role "keyword".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-

main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 361); [backlink](#)

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 387); [backlink](#)

Unknown interpreted text role "keyword".

For example:

```
>>> def bool_return():
...     try:
...         return True
...     finally:
...         return False
... 
```

```
>>> bool_return()
False
```

A more complicated example:

```
>>> def divide(x, y):
...     try:
...         result = x / y
...     except ZeroDivisionError:
...         print("division by zero!")
...     else:
...         print("result is", result)
...     finally:
...         print("executing finally clause")
...
>>> divide(2, 1)
result is 2.0
executing finally clause
>>> divide(2, 0)
division by zero!
executing finally clause
>>> divide("2", "1")
executing finally clause
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 3, in divide
TypeError: unsupported operand type(s) for /: 'str' and 'str'
```

As you can see, the `keyword:finally` clause is executed in any event. The `exc:TypeError` raised by dividing two strings is not handled by the `keyword:except` clause and therefore re-raised after the `keyword:finally` clause has been executed.

In real world applications, the `keyword:finally` clause is useful for releasing external resources (such as files or network connections), regardless of whether the use of the resource was successful.

Predefined Clean-up Actions

Some objects define standard clean-up actions to be undertaken when the object is no longer needed, regardless of whether or not the operation using the object succeeded or failed. Look at the following example, which tries to open a file and print its contents to the screen.

```
for line in open("myfile.txt"):
    print(line, end="")
```

The problem with this code is that it leaves the file open for an indeterminate amount of time after this part of the code has finished executing. This is not an issue in simple scripts, but can be a problem for larger applications. The `keyword:with` statement allows objects like files to be used in a way that ensures they are always cleaned up promptly and correctly.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 452); [backlink](#)

Unknown interpreted text role "keyword".

```
with open("myfile.txt") as f:
    for line in f:
        print(line, end="")
```

After the statement is executed, the file *f* is always closed, even if a problem was encountered while processing the lines. Objects which, like files, provide predefined clean-up actions will indicate this in their documentation.

Raising and Handling Multiple Unrelated Exceptions

There are situations where it is necessary to report several exceptions that have occurred. This is often the case in concurrency frameworks, when several tasks may have failed in parallel, but there are also other use cases where it is desirable to continue execution and collect multiple errors rather than raise the first exception.

The builtin `exc: 'ExceptionGroup'` wraps a list of exception instances so that they can be raised together. It is an exception itself, so it can be caught like any other exception.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\tutorial\[cpython-main] [Doc] [tutorial]errors.rst, line 478); [backlink](#)

Unknown interpreted text role "exc".

```
>>> def f():
...     excs = [OSError('error 1'), SystemError('error 2')]
...     raise ExceptionGroup('there were problems', excs)
...
>>> f()
+ Exception Group Traceback (most recent call last):
+ | File "<stdin>", line 1, in <module>
+ | File "<stdin>", line 3, in f
+ | ExceptionGroup: there were problems
+ +----- 1 -----
+ | OSError: error 1
+ +----- 2 -----
+ | SystemError: error 2
+ +-----
>>> try:
...     f()
... except Exception as e:
...     print(f'caught {type(e)}: {e}')
...
caught <class 'ExceptionGroup':> e
>>>
```

By using `except*` instead of `except`, we can selectively handle only the exceptions in the group that match a certain type. In the following example, which shows a nested exception group, each `except*` clause extracts from the group exceptions of a certain type while letting all other exceptions propagate to other clauses and eventually to be reraised.

```
>>> def f():
...     raise ExceptionGroup("group1",
...                           [OSError(1),
...                            SystemError(2),
...                            ExceptionGroup("group2",
...                                            [OSError(3), RecursionError(4)])])
...
>>> try:
...     f()
... except* OSError as e:
...     print("There were OSErrors")
... except* SystemError as e:
...     print("There were SystemErrors")
...
There were OSErrors
There were SystemErrors
+ Exception Group Traceback (most recent call last):
+ | File "<stdin>", line 2, in <module>
+ | File "<stdin>", line 2, in f
+ | ExceptionGroup: group1
+ +----- 1 -----
+ | ExceptionGroup: group2
+ +----- 1 -----
+ | RecursionError: 4
```

```
+-----  
>>>
```

Note that the exceptions nested in an exception group must be instances, not types. This is because in practice the exceptions would typically be ones that have already been raised and caught by the program, along the following pattern:

```
>>> excs = []  
... for test in tests:  
...     try:  
...         test.run()  
...     except Exception as e:  
...         excs.append(e)  
...  
>>> if excs:  
...     raise ExceptionGroup("Test Failures", excs)  
...
```
