

# Scalable Vector Extension support for AArch64 Linux

Author: Dave Martin <[Dave.Martin@arm.com](mailto:Dave.Martin@arm.com)>

Date: 4 August 2017

This document outlines briefly the interface provided to userspace by Linux in order to support use of the ARM Scalable Vector Extension (SVE).

This is an outline of the most important features and issues only and not intended to be exhaustive.

This document does not aim to describe the SVE architecture or programmer's model. To aid understanding, a minimal description of relevant programmer's model features for SVE is included in Appendix A.

## 1. General

- SVE registers Z0..Z31, P0..P15 and FFR and the current vector length VL, are tracked per-thread.
- The presence of SVE is reported to userspace via HWCAP\_SVE in the aux vector AT\_HWCAP entry. Presence of this flag implies the presence of the SVE instructions and registers, and the Linux-specific system interfaces described in this document. SVE is reported in /proc/cpuinfo as "sve".
- Support for the execution of SVE instructions in userspace can also be detected by reading the CPU ID register ID\_AA64PFR0\_EL1 using an MRS instruction, and checking that the value of the SVE field is nonzero. [3]

It does not guarantee the presence of the system interfaces described in the following sections: software that needs to verify that those interfaces are present must check for HWCAP\_SVE instead.

- On hardware that supports the SVE2 extensions, HWCAP2\_SVE2 will also be reported in the AT\_HWCAP2 aux vector entry. In addition to this, optional extensions to SVE2 may be reported by the presence of:

HWCAP2\_SVE2 HWCAP2\_SVEAES HWCAP2\_SVEPMULL HWCAP2\_SVEBITPERM  
HWCAP2\_SVESHA3 HWCAP2\_SVESM4

This list may be extended over time as the SVE architecture evolves.

These extensions are also reported via the CPU ID register ID\_AA64ZFR0\_EL1, which userspace can read using an MRS instruction. See elf\_hwcaps.txt and cpu-feature-registers.txt for details.

- Debuggers should restrict themselves to interacting with the target via the NT\_ARM\_SVE regset. The recommended way of detecting support for this regset is to connect to a target process first and then attempt a ptrace(PTRACE\_GETREGSET, pid, NT\_ARM\_SVE, &iiov).
- Whenever SVE scalable register values (Zn, Pn, FFR) are exchanged in memory between userspace and the kernel, the register value is encoded in memory in an endianness-invariant layout, with bits  $[(8 * i + 7) : (8 * i)]$  encoded at byte offset  $i$  from the start of the memory representation. This affects for example the signal frame (struct sve\_context) and ptrace interface (struct user\_sve\_header) and associated data.

Beware that on big-endian systems this results in a different byte order than for the FPSIMD V-registers, which are stored as single host-endian 128-bit values, with bits  $[(127 - 8 * i) : (120 - 8 * i)]$  of the register encoded at byte offset  $i$ . (struct fpsimd\_context, struct user\_fpsimd\_state).

## 2. Vector length terminology

The size of an SVE vector (Z) register is referred to as the "vector length".

To avoid confusion about the units used to express vector length, the kernel adopts the following conventions:

- Vector length (VL) = size of a Z-register in bytes
- Vector quadwords (VQ) = size of a Z-register in units of 128 bits

(So,  $VL = 16 * VQ$ .)

The VQ convention is used where the underlying granularity is important, such as in data structure definitions. In most other situations, the VL convention is used. This is consistent with the meaning of the "VL" pseudo-register in the SVE instruction set architecture.

## 3. System call behaviour

- On syscall, V0..V31 are preserved (as without SVE). Thus, bits [127:0] of Z0..Z31 are preserved. All other bits of Z0..Z31, and all of P0..P15 and FFR become unspecified on return from a syscall.
- The SVE registers are not used to pass arguments to or receive results from any syscall.
- In practice the affected registers/bits will be preserved or will be replaced with zeros on return from a syscall, but userspace

should not make assumptions about this. The kernel behaviour may vary on a case-by-case basis.

- All other SVE state of a thread, including the currently configured vector length, the state of the PR\_SVE\_VL\_INHERIT flag, and the deferred vector length (if any), is preserved across all syscalls, subject to the specific exceptions for `execve()` described in section 6.

In particular, on return from a `fork()` or `clone()`, the parent and new child process or thread share identical SVE configuration, matching that of the parent before the call.

## 4. Signal handling

- A new signal frame record `sve_context` encodes the SVE registers on signal delivery. [1]
- This record is supplementary to `fpsimd_context`. The FPSR and FPCR registers are only present in `fpsimd_context`. For convenience, the content of V0..V31 is duplicated between `sve_context` and `fpsimd_context`.
- The signal frame record for SVE always contains basic metadata, in particular the thread's vector length (in `sve_context.vl`).
- The SVE registers may or may not be included in the record, depending on whether the registers are live for the thread. The registers are present if and only if `sve_context.head.size >= SVE_SIG_CONTEXT_SIZE(sve_vl_from_vl(sve_context.vl))`.
- If the registers are present, the remainder of the record has a vl-dependent size and layout. Macros `SVE_SIG_*` are defined [1] to facilitate access to the members.
- Each scalable register (Zn, Pn, FFR) is stored in an endianness-invariant layout, with bits  $[(8 * i + 7) : (8 * i)]$  stored at byte offset `i` from the start of the register's representation in memory.
- If the SVE context is too big to fit in `sigcontext.__reserved[]`, then extra space is allocated on the stack, an `extra_context` record is written in `__reserved[]` referencing this space. `sve_context` is then written in the extra space. Refer to [1] for further details about this mechanism.

## 5. Signal return

When returning from a signal handler:

- If there is no `sve_context` record in the signal frame, or if the record is present but contains no register data as described in the previous section, then the SVE registers/bits become non-live and take unspecified values.
- If `sve_context` is present in the signal frame and contains full register data, the SVE registers become live and are populated with the specified data. However, for backward compatibility reasons, bits [127:0] of Z0..Z31 are always restored from the corresponding members of `fpsimd_context.vregs[]` and not from `sve_context`. The remaining bits are restored from `sve_context`.
- Inclusion of `fpsimd_context` in the signal frame remains mandatory, irrespective of whether `sve_context` is present or not.
- The vector length cannot be changed via signal return. If `sve_context.vl` in the signal frame does not match the current vector length, the signal return attempt is treated as illegal, resulting in a forced SIGSEGV.

## 6. prctl extensions

Some new `prctl()` calls are added to allow programs to manage the SVE vector length:

`prctl(PR_SVE_SET_VL, unsigned long arg)`

Sets the vector length of the calling thread and related flags, where `arg == vl | flags`. Other threads of the calling process are unaffected.

`vl` is the desired vector length, where `sve_vl_valid(vl)` must be true.

flags:

`PR_SVE_VL_INHERIT`

Inherit the current vector length across `execve()`. Otherwise, the vector length is reset to the system default at `execve()`. (See Section 9.)

`PR_SVE_SET_VL_ONEXEC`

Defer the requested vector length change until the next `execve()` performed by this thread.

The effect is equivalent to implicit execution of the following call immediately after the next `execve()` (if any) by the thread:

`prctl(PR_SVE_SET_VL, arg & ~PR_SVE_SET_VL_ONEXEC)`

This allows launching of a new program with a different vector length, while avoiding runtime side effects in the caller.

Without `PR_SVE_SET_VL_ONEXEC`, the requested change takes effect immediately.

Return value: a nonnegative on success, or a negative value on error:

EINVAL: SVE not supported, invalid vector length requested, or invalid flags.

On success:

- Either the calling thread's vector length or the deferred vector length to be applied at the next `execve()` by the thread (dependent on whether `PR_SVE_SET_VL_ONEXEC` is present in `arg`), is set to the largest value supported by the system that is less than or equal to `vl`. If `vl == SVE_VL_MAX`, the value set will be the largest value supported by the system.
- Any previously outstanding deferred vector length change in the calling thread is cancelled.
- The returned value describes the resulting configuration, encoded as for `PR_SVE_GET_VL`. The vector length reported in this value is the new current vector length for this thread if `PR_SVE_SET_VL_ONEXEC` was not present in `arg`; otherwise, the reported vector length is the deferred vector length that will be applied at the next `execve()` by the calling thread.
- Changing the vector length causes all of `P0..P15`, `FFR` and all bits of `Z0..Z31` except for `Z0` bits `[127:0] .. Z31` bits `[127:0]` to become unspecified. Calling `PR_SVE_SET_VL` with `vl` equal to the thread's current vector length, or calling `PR_SVE_SET_VL` with the `PR_SVE_SET_VL_ONEXEC` flag, does not constitute a change to the vector length for this purpose.

`prctl(PR_SVE_GET_VL)`

Gets the vector length of the calling thread.

The following flag may be OR-ed into the result:

`PR_SVE_VL_INHERIT`

Vector length will be inherited across `execve()`.

There is no way to determine whether there is an outstanding deferred vector length change (which would only normally be the case between a `fork()` or `vfork()` and the corresponding `execve()` in typical use).

To extract the vector length from the result, bitwise and it with `PR_SVE_VL_LEN_MASK`.

Return value: a nonnegative value on success, or a negative value on error:

EINVAL: SVE not supported.

## 7. ptrace extensions

- A new regset `NT_ARM_SVE` is defined for use with `PTRACE_GETREGSET` and `PTRACE_SETREGSET`.

Refer to [2] for definitions.

The regset data starts with struct `user_sve_header`, containing:

`size`

Size of the complete regset, in bytes. This depends on `vl` and possibly on other things in the future.

If a call to `PTRACE_GETREGSET` requests less data than the value of `size`, the caller can allocate a larger buffer and retry in order to read the complete regset.

`max_size`

Maximum size in bytes that the regset can grow to for the target thread. The regset won't grow bigger than this even if the target thread changes its vector length etc.

`vl`

Target thread's current vector length, in bytes.

`max_vl`

Maximum possible vector length for the target thread.

`flags`

either

`SVE_PT_REGS_FPSIMD`

SVE registers are not live (GETREGSET) or are to be made non-live (SETREGSET).

The payload is of type struct user\_fpsimd\_state, with the same meaning as for NT\_PRFPREG, starting at offset SVE\_PT\_FPSIMD\_OFFSET from the start of user\_sve\_header.

Extra data might be appended in the future: the size of the payload should be obtained using SVE\_PT\_FPSIMD\_SIZE(vq, flags).

vq should be obtained using sve\_vq\_from\_vl(vl).

or

SVE\_PT\_REGS\_SVE

SVE registers are live (GETREGSET) or are to be made live (SETREGSET).

The payload contains the SVE register data, starting at offset SVE\_PT\_SVE\_OFFSET from the start of user\_sve\_header, and with size SVE\_PT\_SVE\_SIZE(vq, flags);

... OR-ed with zero or more of the following flags, which have the same meaning and behaviour as the corresponding PR\_SET\_VL\_\* flags:

SVE\_PT\_VL\_INHERIT

SVE\_PT\_VL\_ONEXEC (SETREGSET only).

- The effects of changing the vector length and/or flags are equivalent to those documented for PR\_SVE\_SET\_VL. The caller must make a further GETREGSET call if it needs to know what VL is actually set by SETREGSET, unless it is known in advance that the requested VL is supported.
- In the SVE\_PT\_REGS\_SVE case, the size and layout of the payload depends on the header fields. The SVE\_PT\_SVE\_\*( ) macros are provided to facilitate access to the members.
- In either case, for SETREGSET it is permissible to omit the payload, in which case only the vector length and flags are changed (along with any consequences of those changes).
- For SETREGSET, if an SVE\_PT\_REGS\_SVE payload is present and the requested VL is not supported, the effect will be the same as if the payload were omitted, except that an EIO error is reported. No attempt is made to translate the payload data to the correct layout for the vector length actually set. The thread's FPSIMD state is preserved, but the remaining bits of the SVE registers become unspecified. It is up to the caller to translate the payload layout for the actual VL and retry.
- The effect of writing a partial, incomplete payload is unspecified.

## 8. ELF coredump extensions

- A NT\_ARM\_SVE note will be added to each coredump for each thread of the dumped process. The contents will be equivalent to the data that would have been read if a PTRACE\_GETREGSET of NT\_ARM\_SVE were executed for each thread when the coredump was generated.

## 9. System runtime configuration

- To mitigate the ABI impact of expansion of the signal frame, a policy mechanism is provided for administrators, distro maintainers and developers to set the default vector length for userspace processes:

/proc/sys/abi/sve\_default\_vector\_length

Writing the text representation of an integer to this file sets the system default vector length to the specified value, unless the value is greater than the maximum vector length supported by the system in which case the default vector length is set to that maximum.

The result can be determined by reopening the file and reading its contents.

At boot, the default vector length is initially set to 64 or the maximum supported vector length, whichever is smaller. This determines the initial vector length of the init process (PID 1).

Reading this file returns the current system default vector length.

- At every execve() call, the new vector length of the new process is set to the system default vector length, unless
  - PR\_SVE\_VL\_INHERIT (or equivalently SVE\_PT\_VL\_INHERIT) is set for the calling thread, or
  - a deferred vector length change is pending, established via the PR\_SVE\_SET\_VL\_ONEXEC flag (or SVE\_PT\_VL\_ONEXEC).
- Modifying the system default vector length does not affect the vector length of any existing process or thread that does not make an execve() call.

## Appendix A. SVE programmer's model (informative)

This section provides a minimal description of the additions made by SVE to the ARMv8-A programmer's model that are relevant to this document.

Note: This section is for information only and not intended to be complete or to replace any architectural specification.

### A.1. Registers

In A64 state, SVE adds the following:

- 32 8VL-bit vector registers Z0..Z31 For each Zn, Zn bits [127:0] alias the ARMv8-A vector register Vn.

A register write using a Vn register name zeros all bits of the corresponding Zn except for bits [127:0].

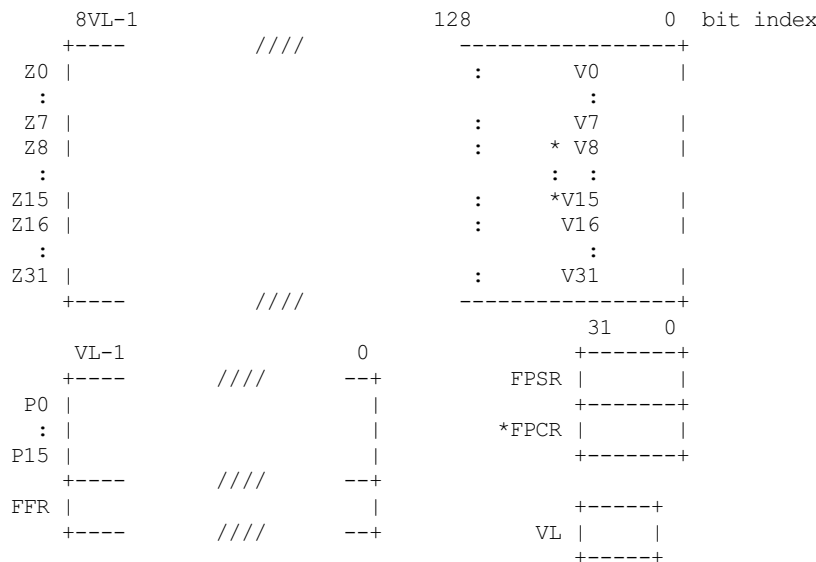

- 16 VL-bit predicate registers P0..P15
- 1 VL-bit special-purpose predicate register FFR (the "first-fault register")
- a VL "pseudo-register" that determines the size of each vector register

The SVE instruction set architecture provides no way to write VL directly. Instead, it can be modified only by EL1 and above, by writing appropriate system registers.

- The value of VL can be configured at runtime by EL1 and above:  $16 \leq VL \leq VL_{max}$ , where VL must be a multiple of 16.
- The maximum vector length is determined by the hardware:  $16 \leq VL_{max} \leq 256$ .

(The SVE architecture specifies 256, but permits future architecture revisions to raise this limit.)

- FPSR and FPCR are retained from ARMv8-A, and interact with SVE floating-point operations in a similar way to the way in which they interact with ARMv8 floating-point operations:

(\*) callee-save:

This only applies to bits [63:0] of Z-/V-registers. FPCR contains callee-save and caller-save bits. See [4] for details.

### A.2. Procedure call standard

The ARMv8-A base procedure call standard is extended as follows with respect to the additional SVE register state:

- All SVE register bits that are not shared with FP/SIMD are caller-save.
- Z8 bits [63:0] .. Z15 bits [63:0] are callee-save.

This follows from the way these bits are mapped to V8..V15, which are caller- save in the base procedure call standard.

## Appendix B. ARMv8-A FP/SIMD programmer's model

Note: This section is for information only and not intended to be complete or to replace any architectural specification.

Refer to [4] for more information.

ARMv8-A defines the following floating-point / SIMD register state:

- 32 128-bit vector registers V0..V31
- 2 32-bit status/control registers FPSR, FPCR

(\*) callee-save:

This only applies to bits [63:0] of V-registers. FPCR contains a mixture of callee-save and caller-save bits.
