

Soak Test serve_hostnames

This directory contains the source for a soak test `serve_hostnames` which performs the following actions when used with the GCE provider:

- A connection is established to the master of the cluster identified from the current context set in `$HOME/.kube/.kubeconfig`.
- The nodes available on the cluster are enumerated (say N nodes).
- On each node, M pods are created (by default 1). The pod encapsulates the `serve_hostnames` image which simply returns the name of the pod in response to a `GET` request. The pods are created individually (i.e. not with a replication controller).
- A service is created which maps to these pods.
- The program makes I iterations (default 1) where it issues $Q \times N \times M$ queries (Q default is 10) via the service proxy interface at the master.
- The program verifies that every pod (and thus every node) responded to at least one query (the average should be about Q).
- The time taken to perform various operations is reported and some operations are re-tried if they failed.

Run the following command:

```
./serve_hostnames
```

Here is some representative output:

```
I0326 14:21:04.179893    11434 serve_hostnames.go:60] Starting serve_hostnames soak

hostnames-8145/server-hostnames

```

The pods are named with *-N-M* suffixes which identify the number of the node *N* and the number of the pod *M* on that node. Notice that in this run the pod (number 0) running on node 3 did not respond to any queries.

The number of iterations to perform for issuing queries can be changed from the default of 1 to some higher value e.g. `--up_to=3` and the number of pods per node can also be changed e.g. `--pods_per_node=2` :

```
./serve_hostnames --up_to=3 --pods_per_node=2
```

The output is similar to this:

```

I0326 14:27:27.584378    11808 serve_hostnames.go:60] Starting serve_hostnames soak

```

Notice here that for the first two iterations neither of the pods on node 2 responded but by the third iteration responses were received from all nodes.

For a soak test use `--up_to=-1` which will loop indefinitely.

Note that this is not designed to be a performance test. The goal for this program is to provide an easy way to have a soak test that can run indefinitely an exercise enough of Kubernetes' functionality to be confident that the cluster is still up and healthy. The reported QPS mainly indicates latency to the master since the proxy requests are issued (deliberately) in a serial manner.

A more detailed report can be produced with `--v=4` which measures the time taken to perform various operations and it also reports the distribution of responses received from the pods. In the example below we see that the pod

on node 0 returned 18 responses, the pod on node 1 returned 10 responses and the pod on node 3 returned 12 responses and the pod on node 2 did not respond at all.

```
./serve_hostnames --v=4
```

The output is similar to this:

```
I0326 14:33:26.020917    12099 serve_hostnames.go:60] Starting serve_hostnames soak
