

# ejson

[Source code of released version](#) | [Source code of development version](#)

---

EJSON is an extension of JSON to support more types. It supports all JSON-safe types, as well as:

- **Date** - JavaScript `Date`
- **Binary** - JavaScript `Uint8Array` or the result of [EJSON.newBinary](#)
- **User-defined types** - see [EJSON.addType](#)

All EJSON serializations are also valid JSON. For example an object with a date and a binary buffer would be serialized in EJSON as:

```
{
  "d": {"$date": 1358205756553},
  "b": {"$binary": "c3VyZS4="}
}
```

For more details, see the [EJSON section](#) of the Meteor docs.
