

UniValue

Summary

A universal value class, with JSON encoding and decoding.

UniValue is an abstract data type that may be a null, boolean, string, number, array container, or a key/value dictionary container, nested to an arbitrary depth.

This class is aligned with the JSON standard, RFC 7159.

Library usage

This is a fork of univalue used by Bitcoin Core. It is not maintained for usage by other projects. Notably, the API may break in non-backward-compatible ways.

Other projects looking for a maintained library should use the upstream univalue at <https://github.com/jgarzik/univalue>.
