

audit-argument-checks

This package causes Meteor to require that all arguments passed to methods and publish functions are checked. Any method that does not pass each one of its arguments to `check` will throw an error, which will be logged on the server and which will appear to the client as a `500 Internal server error`. This is a simple way to help ensure that your app has complete check coverage.

Methods and publish functions that do not need to validate their arguments can simply run `check(arguments, [Match.Any])` to satisfy the `audit-argument-checks` coverage checker.
