

# Deploying to Aerobatic

Aerobatic is a specialized static site host. You can easily deploy your Gatsby site to Aerobatic with the following steps:

1. Install the Aerobatic CLI:

```
npm install aerobatic-cli -g
```

2. Create a new Aerobatic site at the root of your Gatsby project:

```
aero create --name <your-site-name>
```

3. Deploy your Gatsby build output:

```
aero deploy --directory public
```

Your site will be ready on their CDN at <https://<your-site-name>.aerobaticapp.com> in a matter of seconds.

There are some additional HTTP header optimizations you can configure in your `aerobatic.yml` file:

`deploy:`

```
# Note with below setting it is not necessary to pass --directory to aero deploy command
directory: public
# Turn off the Aerobatic asset fingerprinting since Gatsby already does this
optimizer:
  fingerprintAssets: false
```

`plugins:`

```
# Force aggressive 1yr max-age header for all .js and .js.map requests
- name: http-headers
  path: ["/*.js", "/*.js.map"]
  options:
    "Cache-Control": "public, max-age=31536000"
- name: webpage
```
