

Set the runtime locale manually

The initial installation of Angular already contains locale data for English in the United States (**en-US**). The Angular CLI automatically includes the locale data and sets the **LOCALE_ID** value when you use the **--localize** option with **ng build** command.

To manually set the runtime locale of an application to one other than the automatic value, complete the following actions.

1. Search for the Unicode locale ID in the language-locale combination in the Angular repository.
2. Set the **LOCALE_ID** token.

The following example sets the value of **LOCALE_ID** to **fr** for French.
