

## Pushing changes into the Angular tree

Please see Using git with Angular repositories for details about how we maintain a linear commit history and the rules for committing.

As a contributor, see the instructions in CONTRIBUTING.md.

## Change approvals

Change approvals in our monorepo are managed via PullApprove and are configured via the `.pullapprove.yml` file.

## Merging

Once a change has all of the required approvals, either the last approver or the PR author (if PR author has the project collaborator status) should mark the PR with the `action: merge` label and the correct target label. This signals to the caretaker that the PR should be merged. See merge instructions.

## Who is the Caretaker?

See this explanation.
