

Checksums

Starting in early 2012, metadata checksums were added to all major ext4 and jbd2 data structures. The associated feature flag is `metadata_csum`. The desired checksum algorithm is indicated in the superblock, though as of October 2012 the only supported algorithm is `crc32c`. Some data structures did not have space to fit a full 32-bit checksum, so only the lower 16 bits are stored. Enabling the 64bit feature increases the data structure size so that full 32-bit checksums can be stored for many data structures. However, existing 32-bit filesystems cannot be extended to enable 64bit mode, at least not without the experimental `resize2fs` patches to do so.

Existing filesystems can have checksumming added by running `tune2fs -O metadata_csum` against the underlying device. If `tune2fs` encounters directory blocks that lack sufficient empty space to add a checksum, it will request that you run `e2fsck -D` to have the directories rebuilt with checksums. This has the added benefit of removing slack space from the directory files and rebalancing the htree indexes. If you `_ignore_` this step, your directories will not be protected by a checksum!

The following table describes the data elements that go into each type of checksum. The checksum function is whatever the superblock describes (`crc32c` as of October 2013) unless noted otherwise.

Metadata	Length	Ingredients
Superblock	__le32	The entire superblock up to the checksum field. The UUID lives inside the superblock.
MMP	__le32	UUID + the entire MMP block up to the checksum field.
Extended Attributes	__le32	UUID + the entire extended attribute block. The checksum field is set to zero.
Directory Entries	__le32	UUID + inode number + inode generation + the directory block up to the fake entry enclosing the checksum field.
HTREE Nodes	__le32	UUID + inode number + inode generation + all valid extents + HTREE tail. The checksum field is set to zero.
Extents	__le32	UUID + inode number + inode generation + the entire extent block up to the checksum field.
Bitmaps	__le32 or __le16	UUID + the entire bitmap. Checksums are stored in the group descriptor, and truncated if the group descriptor size is 32 bytes (i.e. ^64bit)
Inodes	__le32	UUID + inode number + inode generation + the entire inode. The checksum field is set to zero. Each inode has its own checksum.
Group Descriptors	__le16	If <code>metadata_csum</code> , then UUID + group number + the entire descriptor; else if <code>gdt_csum</code> , then <code>crc16(UUID + group number + the entire descriptor)</code> . In all cases, only the lower 16 bits are stored.
