

React Portal component

Portal

The portal component renders its children into a new “subtree” outside of the current DOM hierarchy.

The children of the portal component will be appended to the **container** specified. The component is used internally by the **Modal** and **Popper** components.

```
{{“component”: “modules/components/ComponentLinkHeader.js”, “design”:  
false}}
```

Example

```
{{“demo”: “SimplePortal.js”}}
```

Server-side

React doesn’t support the **createPortal()** API on the server. You have to wait for the client-side hydration to see the children.
