## **Path Parameters and Numeric Validations**

The same way you can declare more validations and metadata for query parameters with <code>Query</code> , you can declare the same type of validations and metadata for path parameters with <code>Path</code> .

#### **Import Path**

```
First, import Path from fastapi:

=== "Python 3.6 and above"

'``Python hl_lines="3"
{!> ../../../docs_src/path_params_numeric_validations/tutorial001.py!}

=== "Python 3.10 and above"

'``Python hl_lines="1"
{!> ../../../docs_src/path_params_numeric_validations/tutorial001_py310.py!}
```

#### **Declare metadata**

You can declare all the same parameters as for <code>Query</code> .

For example, to declare a title metadata value for the path parameter item id you can type:

=== "Python 3.6 and above"

```
```Python hl_lines="10"
{!> ../../docs_src/path_params_numeric_validations/tutorial001.py!}
```
```

=== "Python 3.10 and above"

```
```Python hl_lines="8"
{!> ../../docs_src/path_params_numeric_validations/tutorial001_py310.py!}
```
```

 $\verb| !!!$  note A path parameter is always required as it has to be part of the path.

```
So, you should declare it with `...` to mark it as required.

Nevertheless, even if you declared it with `None` or set a default value, it would not affect anything, it would still be always required.
```

# Order the parameters as you need

Let's say that you want to declare the query parameter q as a required str.

And you don't need to declare anything else for that parameter, so you don't really need to use Query .

But you still need to use Path for the item id path parameter.

Python will complain if you put a value with a "default" before a value that doesn't have a "default".

But you can re-order them, and have the value without a default (the query parameter q ) first.

It doesn't matter for **FastAPI**. It will detect the parameters by their names, types and default declarations ( <code>Query</code> , <code>Path</code> , etc), it doesn't care about the order.

So, you can declare your function as:

```
{!../../docs_src/path_params_numeric_validations/tutorial002.py!}
```

## Order the parameters as you need, tricks

If you want to declare the <code>q</code> query parameter without a <code>Query</code> nor any default value, and the path parameter <code>item id</code> using <code>Path</code>, and have them in a different order, Python has a little special syntax for that.

Pass \*, as the first parameter of the function.

Python won't do anything with that \* , but it will know that all the following parameters should be called as keyword arguments (key-value pairs), also known as <a href="kwargs">kwargs</a> . Even if they don't have a default value.

```
{!../../docs_src/path_params_numeric_validations/tutorial003.py!}
```

### Number validations: greater than or equal

With Query and Path (and other's you'll see later) you can declare string constraints, but also number constraints.

Here, with ge=1,  $item\_id$  will need to be an integer number " g reater than or e qual" to 1.

```
{!../../docs_src/path_params_numeric_validations/tutorial004.py!}
```

### Number validations: greater than and less than or equal

The same applies for:

- gt: g reater t han
- le: 1 ess than or e qual

```
{!../../docs_src/path_params_numeric_validations/tutorial005.py!}
```

#### Number validations: floats, greater than and less than

Number validations also work for float values.

Here's where it becomes important to be able to declare gt and not just ge. As with it you can require, for example, that a value must be greater than 0, even if it is less than 1.

So, 0.5 would be a valid value. But 0.0 or 0 would not.

And the same for <u>lt</u>.

```
{!../../docs_src/path_params_numeric_validations/tutorial006.py!}
```

#### Recap

With Query, Path (and others you haven't seen yet) you can declare metadata and string validations in the same ways as with Query Parameters and String Validations (.internal-link target=\_blank).

And you can also declare numeric validations:

- gt: g reater t han
- ge: g reater than or e qual
- lt: l ess t han
- le: l ess than or e qual

!!! info Query , Path , and others you will see later are subclasses of a common Param class (that you don't need to use).

And all of them share the same all these same parameters of additional validation and metadata you have seen.

!!! note "Technical Details" When you import Query , Path and others from fastapi , they are actually
functions.

That when called, return instances of classes of the same name.

So, you import `Query`, which is a function. And when you call it, it returns an instance of a class also named `Query`.

These functions are there (instead of just using the classes directly) so that your editor doesn't mark errors about their types.

That way you can use your normal editor and coding tools without having to add custom configurations to disregard those errors.
