Built-in Functions

The Python interpreter has a number of functions and types built into it that are always available. They are listed here in alphabetical order.

role "func".

Unknown interpreted text

Unknown directive type "function".

```
.. function:: abs(x)

Return the absolute value of a number. The argument may be an integer, a floating point number, or an object implementing :meth:`_abs__`. If the argument is a complex number, its magnitude is returned.
```

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 64)

Unknown directive type "function".

```
.. function:: aiter(async_iterable)

Return an :term:`asynchronous iterator` for an :term:`asynchronous iterable`.

Equivalent to calling ``x._aiter_()``.

Note: Unlike :func:`iter`, :func:`aiter` has no 2-argument variant.

.. versionadded:: 3.10
```

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 73)

Unknown directive type "function".

```
.. function:: all(iterable)
Return ``True`` if all elements of the *iterable* are true (or if the iterable
is empty). Equivalent to::

    def all(iterable):
        for element in iterable:
            if not element:
                return False
    return True
```

 $System\ Message: ERROR/3\ (\texttt{D:\noboarding-resources}\spaces) ample-onboarding-resources \cpython-main\cdot\color{brary}\clibrary\clibra$

Unknown directive type "awaitable function".

```
.. awaitablefunction:: anext(async_iterator[, default])

When awaited, return the next item from the given :term:`asynchronous iterator`, or *default* if given and the iterator is exhausted.

This is the async variant of the :func:`next` builtin, and behaves similarly.

This calls the :meth:`~object.__anext__` method of *async_iterator*, returning an :term:`awaitable`. Awaiting this returns the next value of the iterator. If *default* is given, it is returned if the iterator is exhausted, otherwise :exc:`StopAsyncIteration` is raised.

.. versionadded:: 3.10
```

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 100)

Unknown directive type "function".

```
.. function:: any(iterable)
Return ``True`` if any element of the *iterable* is true. If the iterable
is empty, return ``False``. Equivalent to::

   def any(iterable):
        for element in iterable:
            if element:
                return True
   return False
```

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 112)

Unknown directive type "function".

.. function:: ascii(object)

As :func:`repr`, return a string containing a printable representation of an object, but escape the non-ASCII characters in the string returned by :func:`repr` using ``\x``, ``\u``, or ``\U`` escapes. This generates a string similar to that returned by :func:`repr` in Python 2.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 120)

Unknown directive type "function".

```
.. function:: bin(x)

Convert an integer number to a binary string prefixed with "Ob". The result is a valid Python expression. If *x* is not a Python :class: int` object, it has to define an :meth: __index__` method that returns an integer. Some examples:

>>> bin(3)
'Obl1'
>>> bin(-10)
'-Obl010'

If the prefix "Ob" is desired or not, you can use either of the following ways.

>>> format(14, '#b'), format(14, 'b')
('Obl110', '1110')
>>> f'{14:#b}', f'{14:b}'
('Obl110', '1110')
See also :func: format` for more information.
```

Return a Boolean value, i.e. one of True or False. x is converted using the standard reff truth testing procedure <truth>'. If x is false or omitted, this returns False; otherwise, it returns True. The class: bool' class is a subclass of class: int' (see reff typesnumeric'). It cannot be subclassed further. Its only instances are False and True (see reff bltin-boolean-values').

.. versionchanged:: 3.7
 x is now a positional-only parameter.

 $System\ Message: ERROR/3\ (\texttt{D:\onboarding-resources}\ sample-onboarding-resources\ cpython-main\ Doc\ library\ (ppython-main\ (Doc)\ (library)\ functions.rst,\ line\ 156)$

Unknown directive type "function".

.. function:: breakpoint(*args, **kws)

This function drops you into the debugger at the call site. Specifically, it calls :func:`sys.breakpointhook`, passing ``args`` and ``kws`` straight through. By default, ``sys.breakpointhook()`` calls :func:`pdb.set_trace()` expecting no arguments. In this case, it is purely a convenience function so you don't have to explicitly import :mod:`pdb` or type as much code to enter the debugger. However, :func: sys.breakpointhook` can be set to some other function and :func:`breakpoint` will automatically call that, allowing you to drop into the debugger of choice.

- .. audit-event:: builtins.breakpoint breakpointhook breakpoint
- .. versionadded:: 3.7

Return a new array of bytes. The class: bytearray' class is a mutable sequence of integers in the range $0 \le x \le 256$. It has most of the usual methods of mutable sequences, described in ref: typesseq-mutable', as well as most methods that the class: bytes' type has, see ref: bytes-methods'.

Unknown directive type "function".

.. function:: chr(i)

Return the string representing a character whose Unicode code point is the integer *i*. For example, ``chr(97)`` returns the string ``'a'``, while ``chr(8364)`` returns the string ``' 2 ,¬'``. This is the inverse of :func:`ord`.

The valid range for the argument is from 0 through 1,114,111 (0x10FFFF in base 16). :exc:`ValueError` will be raised if *i* is outside that range.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 241)

Unknown directive type "decorator".

.. decorator:: classmethod

Transform a method into a class method.

A class method receives the class as an implicit first argument, just like an instance method receives the instance. To declare a class method, use this idiom::

```
class C:
   @classmethod
   def f(cls, arg1, arg2): ...
```

The ``@classmethod`` form is a function :term:`decorator` -- see :ref:`function` for details.

A class method can be called either on the class (such as ``C.f()``) or on an instance (such as ``C().f()``). The instance is ignored except for its class. If a class method is called for a derived class, the derived class object is passed as the implied first argument.

Class methods are different than C++ or Java static methods. If you want those, see :func:`staticmethod` in this section. For more information on class methods, see :ref:`types`.

- .. versionchanged:: 3.9 Class methods can now wrap other :term:`descriptors <descriptor>` such as :func:`property`.
- .. versionchanged:: 3.10

 Class methods now inherit the method attributes (``__module__``,

 ``__name__`', ``__qualname__`', ``__doc__`` and ``__annotations__``) and have a new ``__wrapped__`` attribute.

 $System\ Message: ERROR/3\ (\texttt{D:\noboarding-resources}) sample-onboarding-resources \verb|\continuous | courses | cours$

Unknown directive type "function".

.. function:: compile(source, filename, mode, flags=0, dont_inherit=False, optimize=-1

Compile the *source* into a code or AST object. Code objects can be executed by :func: `exec` or :func: `eval`. *source* can either be a normal string, a byte string, or an AST object. Refer to the :mod: `ast` module documentation for information on how to work with AST objects.

The *filename* argument should give the file from which the code was read; pass some recognizable value if it wasn't read from a file (``'<string>'`` is commonly used).

The *mode* argument specifies what kind of code must be compiled; it can be ``'exec'`` if *source* consists of a sequence of statements, ``'eval'`` if it consists of a single expression, or `''single'`` if it consists of a single interactive statement (in the latter case, expression statements that evaluate to something other than `None` will be printed).

The optional arguments *flags* and *dont_inherit* control which :ref:`compiler options <ast-compiler-flags>` should be activated and which :ref:`future features <future>` should be allowed. If neither is present (or both are zero) the code is compiled with the same flags that affect the code that is calling :func:`compile`. If the *flags* argument is given and *dont_inherit* is not (or is zero) then the compiler options and the future statements specified by the *flags* argument are used in addition to those that would be used anyway. If *dont_inherit* is a non-zero integer then the *flags* argument is it -- the flags (future features and compiler options) in the surrounding code are ignored.

Compiler options and future statements are specified by bits which can be bitwise ORed together to specify multiple options. The bitfield required to specify a given future feature can be found as the :attr: `__future__. Feature.compiler_flag` attribute on the :class: `~_future__. Feature` instance in the :mod: `_future__` module. :ref: `Compiler flags <ast-compiler-flags>` can be found in :mod: `ast` module, with ``PyCF_`` prefix.

The argument *optimize* specifies the optimization level of the compiler; the default value of ``-l`` selects the optimization level of the interpreter as given by :option: '-0' options. Explicit levels are ``0`` (no optimization; ``_debug__`` is true), ``l`` (asserts are removed, ``_debug__`` is false) or ``2`` (docstrings are removed too).

This function raises :exc:`SyntaxError` if the compiled source is invalid, and :exc:`ValueError` if the source contains null bytes.

If you want to parse Python code into its AST representation, see :func:`ast.parse`.

.. audit-event:: compile source, filename compile

Raises an :ref:`auditing event <auditing>```compile`` with arguments ``source`` and ``filename``. This event may also be raised by implicit compilation.

.. note:

When compiling a string with multi-line code in ``'single'`` or ``'eval'`` mode, input must be terminated by at least one newline character. This is to facilitate detection of incomplete and complete statements in the :mod:'code' module.

.. warning::

It is possible to crash the Python interpreter with a sufficiently large/complex string when compiling to an AST object due to stack depth limitations in Python's AST compiler.

.. versionchanged:: 3.2
Allowed use of Windows and Mac newlines. Also, input in ``'exec'`` mode does not have to end in a newline anymore. Added the *optimize* parameter.

```
    versionchanged:: 3.5
        Previously, :exc:`TypeError` was raised when null bytes were encountered in *source*.

    versionadded:: 3.8
        ``ast.PyCF_ALLOW_TOP_LEVEL_AWAIT`` can now be passed in flags to enable support for top-level ``await``, ``async for``, and ``async with``.
```

Return a complex number with the value $real + imag^*1j$ or convert a string or number to a complex number. If the first parameter is a string, it will be interpreted as a complex number and the function must be called without a second parameter. The second parameter can never be a string. Each argument may be any numeric type (including complex). If imag is omitted, it defaults to zero and the constructor serves as a numeric conversion like class: int' and class: float'. If both arguments are omitted, returns 0j.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 408)

Unknown directive type "function".

```
.. function:: dir([object])
```

Without arguments, return the list of names in the current local scope. With an argument, attempt to return a list of valid attributes for that object.

If the object has a method named :meth:`_dir_`, this method will be called and must return the list of attributes. This allows objects that implement a custom :func:`_getattr_` or :func:`_getattr_` function to customize the way :func: 'dir' reports their attributes.

If the object does not provide :meth: `_dir_`, the function tries its best to gather information from the object's :attr: `~object._dict_` attribute, if defined, from its type object. The resulting list is not necessarily complete and may be inaccurate when the object has a custom :func: `_getattr_`.

The default :func:`dir` mechanism behaves differently with different types of objects, as it attempts to produce the most relevant, rather than complete, information:

- $\mbox{^{\star}}$ If the object is a module object, the list contains the names of the module's attributes.
- * If the object is a type or class object, the list contains the names of its attributes, and recursively of the attributes of its bases.
- * Otherwise, the list contains the object's attributes' names, the names of its class's attributes, and recursively of the attributes of its class's base classes.

The resulting list is sorted alphabetically. For example:

```
>>> import struct
>>> dir()  # show the names in the module namespace  # doctest: +SKIP
['_builtins_', '_name_', 'struct']
>>> dir(struct)  # show the names in the struct module  # doctest: +SKIP
['Struct', '_all_', '_builtins_', '_cached_', '_doc_', '_file_',
    '_initializing_', '_loader_', '_name_', '_package_',
    '_clearcache', 'calcsize', 'error', 'pack', 'pack_into',
    'unpack', 'unpack_from']
>>> class Shape:
...     def _dir_(self):
...     return ['area', 'perimeter', 'location']
>>> dir(s)
['area', 'location', 'perimeter']
```

.. note:

Because :func:`dir` is supplied primarily as a convenience for use at an interactive prompt, it tries to supply an interesting set of names more than it tries to supply a rigorously or consistently defined set of names, and its detailed behavior may change across releases. For example, metaclass attributes are not in the result list when the argument is a class.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main)\Doc\library\(cpython-main)\) (Doc) (library) functions.rst, line 464)

Unknown directive type "function".

```
.. function:: divmod(a, b)
```

Take two (non-complex) numbers as arguments and return a pair of numbers consisting of their quotient and remainder when using integer division. With mixed operand types, the rules for binary arithmetic operators apply. For integers, the result is the same as ``(a // b, a % b)``. For floating point numbers the result is ``(q, a % b)``, where *q* is usually ``math.floor(a / b)`` but may be 1 less than that. In any case ``q * b + a % b`` is very close to *a*, if ``a % b`` is non-zero it has the same sign as *b*, and ``0 <= abs(a % b) < abs(b)``.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main)\((Doc)\) (library) functions.rst, line 476)

Unknown directive type "function".

```
.. function:: enumerate(iterable, start=0)
```

Return an enumerate object. *iterable* must be a sequence, an :term:`iterator`, or some other object which supports iteration.
The :meth:`-iterator.__next__` method of the iterator returned by :func:`enumerate` returns a tuple containing a count (from *start* which defaults to 0) and the values obtained from iterating over *iterable*.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 499)

Unknown directive type "function".

```
.. function:: eval(expression[, globals[, locals]])
```

The arguments are a string and optional globals and locals. If provided, *globals* must be a dictionary. If provided, *locals* can be any mapping object.

The *expression* argument is parsed and evaluated as a Python expression (technically speaking, a condition list) using the *globals* and *locals* dictionaries as global and local namespace. If the *globals* dictionary is present and does not contain a value for the key `_builtins_``, a reference to the dictionary of the built-in module '.mod:`builtins` is inserted under that key before *expression* is parsed. That way you can control what builtins are available to the executed code by inserting your own `_builtins_'` dictionary into *globals* before passing it to :func:`eval`. If the *locals* dictionary is omitted it defaults to the *globals* dictionary. If both dictionaries are omitted, the expression is executed with the *globals* and *locals* in the environment where :func:`eval` is called. Note, *eval()* does not have access to the :term:`nested scopes <nested scope>` (non-locals) in the enclosing environment

```
>>> x = 1
>>> eval('x+1')
2
```

This function can also be used to execute arbitrary code objects (such as those created by :func:`compile`). In this case, pass a code object instead of a string. If the code object has been compiled with ``'exec'`` as the *mode* argument, :func:`eval`\'s return value will be ``None``.

Hints: dynamic execution of statements is supported by the :func:`exec` function. The :func:`globals` and :func:`locals` functions return the current global and local dictionary, respectively, which may be useful to pass around for use by :func:`eval` or :func:`exec`.

If the given source is a string, then leading and trailing spaces and tabs are stripped.

See :func:`ast.literal_eval` for a function that can safely evaluate strings with expressions conta \overline{i} ning only literals.

```
.. audit-event:: exec code_object eval
```

Raises an :ref:`auditing event <auditing>` ``exec`` with the code object as the argument. Code compilation events may also be raised.

.. index:: builtin: exec

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpythonmain\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 550)

Unknown directive type "function".

.. function:: exec(object[, globals[, locals]])

This function supports dynamic execution of Python code. *object* must be either a string or a code object. If it is a string, the string is parsed as a suite of Python statements which is then executed (unless a syntax error occurs). [#] If it is a code object, it is simply executed. In all cases, the code that's executed is expected to be valid as file input (see the section :ref:`file-input` in the Reference Manual). Be aware that the :keyword:`nonlocal`, :keyword:`yield`, and :keyword:`return statements may not be used outside of function definitions even within the context of code passed to the :func:`exec` function. The return value is ``None``.

In all cases, if the optional parts are omitted, the code is executed in the current scope. If only *globals* is provided, it must be a dictionary (and not a subclass of dictionary), which will be used for both the global and the local variables. If *globals* and *locals* are given, they are used for the global and local variables, If provided, *locals* can be any mapping object. Remember that at the module level, globals and locals are the same dictionary. If exec gets two separate objects as *globals* and *locals*, the code will be executed as if it were embedded in a class definition.

If the *globals* dictionary does not contain a value for the key ``_builtins__``, a reference to the dictionary of the built-in module :mod:`builtins` is inserted under that key. That way you can control what builtins are available to the executed code by inserting your own ``_builtins__`` dictionary into *globals* before passing it to :func:`exec`.

.. audit-event:: exec code object exec

Raises an :ref:`auditing event <auditing>` ``exec`` with the code object as the argument. Code compilation events may also be raised.

The built-in functions :func:`globals` and :func:`locals` return the current global and local dictionary, respectively, which may be useful to pass around for use as the second and third argument to :func:`exec`.

The default *locals* act as described for function :func:`locals` below: modifications to the default *locals* dictionary should not eattempted. Pass an explicit *locals* dictionary if you need to see effects of the code on *locals* after function :func:`exec` returns.

System Message: ERROR/3 (D:\onb oarding-resources\sample-on ain\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 598)

Unknown directive type "function".

.. function:: filter(function, iterable)

Construct an iterator from those elements of *iterable* for which *function* returns true. *iterable* may be either a sequence, a container which supports iteration, or an iterator. If *function* is ``None``, the id function is assumed, that is, all elements of *iterable* that are false are

Note that ``filter(function, iterable)`` is equivalent to the generator expression ``(item for item in iterable if function(item))` if function is
not ``None`` and ``(item for item in iterable if item)`` if function is

See :func: itertools.filterfalse' for the complementary function that returns elements of *iterable* for which *function* returns false.

Unknown directive type "index".

```
.. index::
  single: NaN
  single: Infinity
```

Return a floating point number constructed from a number or string x.

If the argument is a string, it should contain a decimal number, optionally preceded by a sign, and optionally embedded in whitespace. The optional sign may be '+' or '-'; a '+' sign has no effect on the value produced. The argument may also be a string representing a NaN (not-a-number), or positive or negative infinity. More precisely, the input must conform to the following grammar after leading and trailing whitespace characters are removed:

 $System\,Message:\,ERROR/3\ (\texttt{D:}\nonlineserrors) a sample-onboarding-resources \verb|\cpython-resources|| and the sample-onboarding-resources | and the sample-onboarding-resources|| and t$ ain\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 631)

Unknown directive type "productionlist".

```
.. productionlist:: float
    sign: "+" | "-"
    infinity: "Infinity" | "inf"
    nan: "nan"
    numeric_value: `floatnumber` | `infinity` | `nan`
    numeric_string: [`sign`] `numeric_value`
```

Here floatnumber is the form of a Python floating-point literal, described in ref. floating. Case is not significant, so, for example, "inf", "InFINITY", and "iNfINity" are all acceptable spellings for positive infinity.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 638); backlink

Unknown interpreted text role 'ref'.

Otherwise, if the argument is an integer or a floating point number, a floating point number with the same value (within Python's floating point precision) is returned. If the argument is outside the range of a Python float, an exe: OverflowError will be raised.

Unknown directive type "function".

```
.. function:: format(value[, format_spec])
```

```
Convert a *value* to a "formatted" representation, as controlled by
*format_spec*. The interpretation of *format_spec* will depend on the type
of the *value* argument; however, there is a standard formatting syntax that
is used by most built-in types: :ref:`formatspec`.

The default *format_spec* is an empty string which usually gives the same
effect as calling :func:`str(value) <str>`
A call to ``format(value, format_spec)`` is translated to
``type(value) _ format_ (value, format_spec)`` which bypasses the instance
dictionary when searching for the value's :meth:`_format_` method. A
:exc:`TypeError` exception is raised if the method search reaches
:mod:`object` and the *format_spec* is non-empty, or if either the
*format_spec* or the return value are not strings.

.. versionchanged:: 3.4
   ``object().__format__(format_spec)`` raises :exc:`TypeError`
   if *format_spec* is not an empty string.
```

Return a new :class: frozenset' object, optionally with elements taken from iterable. frozenset is a built-in class. See :class: frozenset' and :ref: types-set' for documentation about this class.

```
.. function:: getattr(object, name[, default])
```

Return the value of the named attribute of *object*. *name* must be a string. If the string is the name of one of the object's attributes, the result is the value of that attribute. For example, ``getattr(x, 'foobar')`` is equivalent to ``x.foobar``. If the named attribute does not exist, *default* is returned if provided, otherwise :exc:`AttributeError` is raised.

.. note:

Since :ref:`private name mangling <private-name-mangling>` happens at compilation time, one must manually mangle a private attribute's (attributes with two leading underscores) name in order to retrieve it with :func: getattr`.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 734)

Unknown directive type "function".

.. function:: globals()

Return the dictionary implementing the current module namespace. For code within functions, this is set when the function is defined and remains the same regardless of where the function is called.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 741)

Unknown directive type "function".

.. function:: hasattr(object, name)

The arguments are an object and a string. The result is ``True`` if the string is the name of one of the object's attributes, ``False`` if not. (This is implemented by calling ``getattr(object, name)`` and seeing whether it raises an :exc:`AttributeError` or not.)

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 749)

Unknown directive type "function".

.. function:: hash(object)

Return the hash value of the object (if it has one). Hash values are integers. They are used to quickly compare dictionary keys during a dictionary lookup. Numeric values that compare equal have the same hash value (even if they are of different types, as is the case for 1 and 1.0).

.. note:

For objects with custom :meth:`_hash_` methods, note that :func:`hash` truncates the return value based on the bit width of the host machine. See :meth:`_hash_` for details.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 762)

Unknown directive type "function".

.. function:: help([object])

Invoke the built-in help system. (This function is intended for interactive use.) If no argument is given, the interactive help system starts on the interpreter console. If the argument is a string, then the string is looked up as the name of a module, function, class, method, keyword, or documentation topic, and a help page is printed on the console. If the argument is any other kind of object, a help page on the object is generated.

Note that if a slash(/) appears in the parameter list of a function when invoking :func: help', it means that the parameters prior to the slash are positional-only. For more info, see :ref: the FAQ entry on positional-only parameters <faq-positional-only-arguments>`.

This function is added to the built-in namespace by the :mod:`site` module.

.. versionchanged:: 3.4
 Changes to :mod:`pydoc` and :mod:`inspect` mean that the reported
 signatures for callables are now more comprehensive and consistent.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 783)

Unknown directive type "function".

.. function:: hex(x)

Convert an integer number to a lowercase hexadecimal string prefixed with "Ox". If *x* is not a Python :class:`int` object, it has to define an :meth:`_index__` method that returns an integer. Some examples:

```
>>> hex(255)
'0xff'
>>> hex(-42)
'-0x2a'
```

If you want to convert an integer number to an uppercase or lower hexadecimal string with prefix or not, you can use either of the following ways:

```
>>> '%#x' % 255, '%x' % 255, '%X' % 255
('0xff', 'ff', 'FF')
>>> format(255, '#x'), format(255, 'x'), format(255, 'X')
('0xff', 'ff', 'FF')
>>> f'(255:#x)', f'(255:x}', f'{255:X}'
('0xff', 'ff', 'FF')
```

See also :func:`format` for more information.

See also :func:`int` for converting a hexadecimal string to an integer using a base of 16.

.. note:

To obtain a hexadecimal string representation for a float, use the :meth: `float.hex` method.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main)\((Doc)\)\((Library)\) functions.rst, line 815)
Unknown directive type "function".

.. function:: id(object)

Return the "identity" of an object. This is an integer which is guaranteed to be unique and constant for this object during its lifetime.

is guaranteed to be unique and constant for this object during its lifetime. Two objects with non-overlapping lifetimes may have the same :func:`id` value.

- .. impl-detail:: This is the address of the object in memory.
- .. audit-event:: builtins.id id id

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 827)

Unknown directive type "function".

.. function:: input([prompt])

If the *prompt* argument is present, it is written to standard output without a trailing newline. The function then reads a line from input, converts it to a string (stripping a trailing newline), and returns that. When EOF is read, :exc: `EOFError` is raised. Example::

```
>>> s = input('--> ')  # doctest: +SKIP
--> Monty Python's Flying Circus
>>> s  # doctest: +SKIP
"Monty Python's Flying Circus"
```

If the :mod:`readline` module was loaded, then :func:`input` will use it to provide elaborate line editing and history features.

.. audit-event:: builtins.input prompt input

Raises an :ref:`auditing event <auditing>` ``builtins.input`` with argument ``prompt`` before reading input

.. audit-event:: builtins.input/result result input

Raises an auditing event ``builtins.input/result`` with the result after successfully reading input.

Return an integer object constructed from a number or string x, or return 0 if no arguments are given. If x defines $\frac{\text{meth'}}{\text{int}}$, int (x) returns x. $_int_{()}$. If x defines $\frac{\text{meth'}}{\text{int}}$, it returns x. $_index_{()}$. If x defines $\frac{\text{meth'}}{\text{int}}$, it returns x. $_index_{()}$. For floating point numbers, this truncates towards zero.

Unknown interpreted text role "meth".

If x is not a number or if base is given, then x must be a string, class; bytes', or class; bytearray' instance representing an ref: integer literal <integers>' in radix base. Optionally, the literal can be preceded by + or - (with no space in between) and surrounded by whitespace. A base-n literal consists of the digits 0 to n-1, with a to z (or A to z) having values 10 to 35. The default base is 10. The allowed values are 0 and 2--36. Base-2, -8, and -16 literals can be optionally prefixed with 0b/0B, 0o/00, or 0x/0x, as with integer literals in code. Base 0 means to interpret exactly as a code literal, so that the actual base is 2, 8, 10, or 16, and so that int ('010', 0) is not legal, while int ('010') is, as well as int ('010', 8).

```
.. function:: isinstance(object, classinfo)

Return ``True`` if the *object* argument is an instance of the *classinfo* argument, or of a (direct, indirect, or :term:`virtual <abstract base class>`) subclass thereof. If *object* is not an object of the given type, the function always returns ``False``. If *classinfo* is a tuple of type objects (or recursively, other such tuples) or a :ref:`types-union` of multiple types, return ``True`` if *object* is an instance of any of the types.

If *classinfo* is not a type or tuple of types and such tuples, a :exc:`TypeError` exception is raised.

.. versionchanged:: 3.10
    *classinfo* can be a :ref:`types-union`.
```

 $System\ Message: ERROR/3\ (\texttt{D:\noboarding-resources}) ample-onboarding-resources \verb|\coc|| to main\ Doc\library\ (\texttt{cpython-main})\ (\texttt{Doc})\ (\texttt{library})\ functions.rst,\ line\ 914)$

Unknown directive type "function".

```
.. function:: issubclass(class, classinfo)

Return ``True`` if *class* is a subclass (direct, indirect, or :term:`virtual <abstract base class>`) of *classinfo*. A class is considered a subclass of itself. *classinfo* may be a tuple of class objects or a :ref:`types-union`, in which case return ``True`` if *class* is a subclass of any entry in *classinfo*. In any other case, a :exc:`TypeError` exception is raised.

.. versionchanged:: 3.10
    *classinfo* can be a :ref:`types-union`.
```

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 927)

Unknown directive type "function".

```
.. function:: iter(object[, sentinel])
```

Return an :term:`iterator` object. The first argument is interpreted very differently depending on the presence of the second argument. Without a second argument, *object* must be a collection object which supports the :term:`iterable` protocol (the :meth:`__iter__` method), or it must support the sequence protocol (the :meth:`__getitem__` method with integer arguments starting at `'O`'). If it does not support either of those protocols, exc:`TypeError` is raised. If the second argument, *sentinel*, is given, then *object* must be a callable object. The iterator created in this case will call *object* with no arguments for each call to its :meth: ~iterator.__next__` method; if the value returned is equal to *sentinel*, :exc:`StopIteration` will be raised, otherwise the value will be returned.

See also :ref:`typeiter`.

One useful application of the second form of :func:`iter` is to build a block-reader. For example, reading fixed-width blocks from a binary database file until the end of file is reached::

from functools import partial with open('mydata.db', 'rb') as f:
 for block in iter(partial(f.read, 64), b''):
 process_block(block)

 $System\ Message: ERROR/3\ (\texttt{D:\noboarding-resources}) ample-onboarding-resources \verb|\continuoux| (python-main)\ (\texttt{Doc})\ (\texttt{library})\ functions.rst,\ line\ 954)$

Unknown directive type "function".

.. function:: len(s)

Return the length (the number of items) of an object. The argument may be a sequence (such as a string, bytes, tuple, list, or range) or a collection (such as a dictionary, set, or frozen set).

.. impl-detail::

``len`` raises :exc:`OverflowError` on lengths larger than :data:`sys.maxsize`, such as :class:`range(2 ** 100) <range>`.

Rather than being a function, 'class' list' is actually a mutable sequence type, as documented in ref. 'typesseq-list' and ref. 'typesseq'.

.. function:: locals()

Update and return a dictionary representing the current local symbol table. Free variables are returned by :func:`locals` when it is called in function blocks, but not in class blocks. Note that at the module level, :func:`locals` and :func:`globals` are the same dictionary.

. note::

The contents of this dictionary should not be modified; changes may not affect the values of local and free variables used by the interpreter.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 985)

Unknown directive type "function".

.. function:: map(function, iterable, ...)

Return an iterator that applies *function* to every item of *iterable*, yielding the results. If additional *iterable* arguments are passed, *function* must take that many arguments and is applied to the items from all iterables in parallel. With multiple iterables, the iterator stops when the shortest iterable is exhausted. For cases where the function inputs are already arranged into argument tuples, see :func:`itertools.starmap`\.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 995)

Unknown directive type "function".

```
.. function:: max(iterable, *[, key, default])
```

```
max(arg1, arg2, *args[, key])

Return the largest item in an iterable or the largest of two or more arguments.

If one positional argument is provided, it should be an :term:`iterable`. The largest item in the iterable is returned. If two or more positional arguments are provided, the largest of the positional arguments is returned.

There are two optional keyword-only arguments. The *key* argument specifies a one-argument ordering function like that used for :meth:`list.sort`. The *default* argument specifies an object to return if the provided iterable is empty. If the iterable is empty and *default* is not provided, a :exc:`ValueError` is raised.

If multiple items are maximal, the function returns the first one encountered. This is consistent with other sort-stability preserving tools such as ``sorted(iterable, key=keyfunc, reverse=True)[0]`` and ``heapq.nlargest(1, iterable, key=keyfunc)``.

.. versionadded:: 3.4

The *default* keyword-only argument.

.. versionchanged:: 3.8

The *key* can be ``None``.
```

Return a "memory view" object created from the given argument. See ref. typememoryview` for more information.

Unknown directive type "function".

```
.. function:: oct(x)
```

Convert an integer number to an octal string prefixed with "0o". The result is a valid Python expression. If *x* is not a Python :class: int` object, it has to define an :meth: __index__` method that returns an integer. For example:

```
>>> oct(8)
'0o10'
>>> oct(-56)
'-0o70'
```

If you want to convert an integer number to an octal string either with the prefix "0o" or not, you can use either of the following ways.

```
>>> '%#o' % 10, '%o' % 10
('0o12', '12')
>>> format(10, '#o'), format(10, 'o')
('0o12', '12')
>>> f'(10:#o)', f'{10:o}'
('0o12', '12')
```

See also :func:`format` for more information.

```
.. index::
    single: file object; open() built-in function
```

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 1107)

Unknown directive type "function".

```
.. function:: open(file, mode='r', buffering=-1, encoding=None, errors=None, newline=None, closefd=True, opener=None
```

Open *file* and return a corresponding :term:`file object`. If the file cannot be opened, an :exc:`OSError` is raised. See :ref:`tut-files` for more examples of how to use this function.

file is a :term:`path-like object` giving the pathname (absolute or relative to the current working directory) of the file to be opened or an integer file descriptor of the file to be wrapped. (If a file descriptor is given, it is closed when the returned I/O object is closed unless *closefd* is set to ``False``.)

mode is an optional string that specifies the mode in which the file is opened. It defaults to ``'r'`` which means open for reading in text mode. Other common values are ``'w'` for writing (truncating the file if it already exists), ``'x'` for exclusive creation, and `''a'`` for appending (which on *some* Unix systems, means that *all* writes append to the end of the file regardless of the current seek position). In text mode, if *encoding* is not specified the encoding used is platform-dependent: `'locale.getpreferredencoding(False)'` is called to get the current locale encoding. (For reading and writing raw bytes use binary mode and leave *encoding* unspecified.) The available modes are:

```
.. _filemodes:
```

.. index::
 pair: file; modes

Character Meaning

```
open for reading (default)

''w'' open for writing, truncating the file first

'x'' open for exclusive creation, failing if the file already exists

'a'' open for writing, appending to the end of file if it exists

binary mode

'tt'' text mode (default)

''+'' open for updating (reading and writing)
```

The default mode is ``'r'`` (open for reading text, a synonym of ``'rt'``) Modes ``'w+b'`` and ``'w+b'`` open and truncate the file. Modes ``'r+'`` and ``'r+b'`` open the file with no truncation.

As mentioned in the :ref:`io-overview`, Python distinguishes between binary and text I/O. Files opened in binary mode (including ``'b'`` in the *mode* argument) return contents as :class:`bytes` objects without any decoding. In text mode (the default, or when ``'t'`` is included in the *mode* argument), the contents of the file are returned as :class: str`, the bytes having been

first decoded using a platform-dependent encoding or using the specified *encoding* if given.

note.

Python doesn't depend on the underlying operating system's notion of text files; all the processing is done by Python itself, and is therefore platform-independent.

buffering is an optional integer used to set the buffering policy. Pass 0 to switch buffering off (only allowed in binary mode), 1 to select line buffering (only usable in text mode), and an integer > 1 to indicate the size in bytes of a fixed-size chunk buffer. When no *buffering* argument is given, the default buffering policy works as follows:

- * Binary files are buffered in fixed-size chunks; the size of the buffer is chosen using a heuristic trying to determine the underlying device's "block size" and falling back on :attr: `io.DEFAULT_BUFFER_SIZE`. On many systems, the buffer will typically be 4096 or 8192 bytes long.
- * "Interactive" text files (files for which :meth:`~io.IOBase.isatty` returns ``True``) use line buffering. Other text files use the policy described above for binary files.

encoding is the name of the encoding used to decode or encode the file. This should only be used in text mode. The default encoding is platform dependent (whatever :func:`locale.getpreferredencoding` returns), but any :term:`text encoding` supported by Python can be used. See the :mod:`codecs` module for the list of supported encodings.

errors is an optional string that specifies how encoding and decoding errors are to be handledãe"this cannot be used in binary mode. A variety of standard error handlers are available (listed under :ref: error-handlers'), though any error handling name that has been registered with :func:'codecs.register_error' is also valid. The standard names include:

- * ``'strict'`` to raise a :exc:`ValueError` exception if there is an encoding error. The default value of ``None`` has the same effect.
- * ``'ignore'`` ignores errors. Note that ignoring encoding errors can lead to data loss.
- * ``'replace'`` causes a replacement marker (such as ``'?'``) to be inserted where there is malformed data.
- * ``'surrogateescape'`` will represent any incorrect bytes as low surrogate code units ranging from U+DC80 to U+DCFF. These surrogate code units will then be turned back into the same bytes when the ``surrogateescape`` error handler is used when writing data. This is useful for processing files in an unknown encoding.
- * ``'xmlcharrefreplace'`` is only supported when writing to a file. Characters not supported by the encoding are replaced with the appropriate XML character reference ``&#nnn;``.
- * ``'backslashreplace'`` replaces malformed data by Python's backslashed escape sequences.
- * ``'namereplace'`` (also only supported when writing) replaces unsupported characters with ``\N{...}`` escape sequences.
- single: universal newlines; open() built-in function
 .. open-newline-parameter:

.. index::

newline controls how :term:`universal newlines` mode works (it only applies to text mode). It can be ``None``, ``'\\n'``, ``'\\n'``, and ``'\\\"``. It works as follows:

- * When reading input from the stream, if *newline* is ``None``, universal newlines mode is enabled. Lines in the input can end in ``'\n'``, ``'\r'``, or ``'\r\n'``, and these are translated into ``'\n'`` before being returned to the caller. If it is ``''`, universal newlines mode is enabled, but line endings are returned to the caller untranslated. If it has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- * When writing output to the stream, if *newline* is ``None``, any ``'\n'`` characters written are translated to the system default line separator, :data:`os.linesep`. If *newline* is ``'!\`` or ``'\n'``, no translation takes place. If *newline* is any of the other legal values, any ``'\n'`` characters written are translated to the given string.

If *closefd* is ``False`` and a file descriptor rather than a filename was given, the underlying file descriptor will be kept open when the file is closed. If a filename is given *closefd* must be ``True`` (the default); otherwise, an error will be raised.

A custom opener can be used by passing a callable as *opener*. The underlying file descriptor for the file object is then obtained by calling *opener* with (*file*, *flags*). *opener* must return an open file descriptor (passing :mod:`os.open` as *opener* results in functionality similar to passing ``None``).

The newly created file is :ref:`non-inheritable <fd inheritance>`.

The following example uses the :ref:`dir_fd <dir_fd>` parameter of the :func:`os.open` function to open a file relative to a given directory::

```
>>> import os
>>> dir fd = os.open('somedir', os.O_RDONLY)
>>> def opener(path, flags):
... return os.open(path, flags, dir_fd=dir_fd)
```

```
>>> with open('spamspam.txt', 'w', opener=opener) as f:
                print('This will be written to somedir/spamspam.txt', file=f)
     >>> os.close(dir fd) # don't leak a file descriptor
The type of :term:`file object` returned by the :func:`open` function
depends on the mode. When :func: open is used to open a file in a text mode (''w''), ''rt'', ''rt'', etc.), it returns a subclass of :class: io.TextIOBase' (specifically :class: io.TextIOWrapper'). When used to open a file in a binary mode with buffering, the returned class is a
subclass of :class:`io.BufferedIOBase`. The exact class varies: in read binary mode, it returns an :class:`io.BufferedReader`; in write binary and
append binary modes, it returns an :class:'io.BufferedWriter', and in read/write mode, it returns an :class:'io.BufferedRandom'. When buffering is
disabled, the raw stream, a subclass of :class:`io.RawIOBase`, :class:`io.FileIO`, is returned.
.. index::
    single: line-buffered I/O
    single: unbuffered I/O
single: buffer size, I/O
     single: I/O control; buffering
    single: binary mode
    single: text mode
    module: sys
See also the file handling modules, such as :mod:`fileinput`, :mod:`io` (where :func:`open` is declared), :mod:`os`, :mod:`os.path`, :mod:`tempfile`,
and .mod. `shutil`
.. audit-event:: open file, mode, flags open
The ''mode'' and ''flags'' arguments may have been modified or inferred from the original call.
.. versionchanged:: 3.3
         * The *opener* parameter was added.
* The ``'x'`` mode was added.
         ^\star :exc: <code>`IOError`</code> used to be raised, it is now an alias of :exc: <code>`OSError`</code> .
         * :exc:`FileExistsError` is now raised if the file opened in exclusive creation mode (``'x'``) already exists.
.. versionchanged:: 3.4
         * The file is now non-inheritable.
.. versionchanged:: 3.5
         * If the system call is interrupted and the signal handler does not raise an
            exception, the function now retries the system call instead of raising an :exc:`InterruptedError` exception (see :pep:`475` for the rationale).

The ``'namereplace'`` error handler was added.
.. versionchanged:: 3.6
          * Support added to accept objects implementing :class: `os.PathLike`.
         * On Windows, opening a console buffer may return a subclass of :class:`io.RawIOBase` other than :class:`io.FileIO`.
.. versionchanged:: 3.11
The ``'U'`` mode has
                     mode has been removed.
```

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 1329)

Unknown directive type "function".

.. function:: ord(c)

Given a string representing one Unicode character, return an integer representing the Unicode code point of that character. For example, ``ord('a')`` returns the integer ``97`` and ``ord('â,¬')`` (Euro sign) returns ``8364``. This is the inverse of :func:`chr`.

 $System\ Message: ERROR/3\ (\texttt{D:\noboarding-resources}) ample-onboarding-resources \verb|\continuoux| (python-main)\ (\texttt{Doc})\ (\texttt{library})\ functions.rst,\ line\ 1337)$

Unknown directive type "function".

```
.. function:: pow(base, exp[, mod])
```

Return *base* to the power *exp*; if *mod* is present, return *base* to the power *exp*, modulo *mod* (computed more efficiently than ``pow(base, exp) % mod``). The two-argument form ``pow(base, exp)`` is equivalent to using the power operator: ``base**exp``.

The arguments must have numeric types. With mixed operand types, the coercion rules for binary arithmetic operators apply. For :class:`int` operands, the result has the same type as the operands (after coercion) unless the second argument is negative; in that case, all arguments are converted to float and a float result is delivered. For example, ``pow(10, 2)`` returns ``100``, but ``pow(10, -2)`` returns ``0.01``. For a negative base of type :class:`int` or :class:`float` and a non-integral exponent, a complex result is delivered. For example, ``pow(-9, 0.5)`` returns a value close to ``31``.

For :class:`int` operands *base* and *exp*, if *mod* is present, *mod* must also be of integer type and *mod* must be nonzero. If *mod* is present and *exp* is negative, *base* must be relatively prime to *mod*. In that case, ``pow(inv_base, -exp, mod)`` is returned, where *inv_base* is an inverse to *base* modulo *mod*.

```
Here's an example of computing an inverse for ``38`` modulo ``97``::
   >>> pow(38, -1, mod=97)
   >>> 23 * 38 % 97 == 1
   True
.. versionchanged:: 3.8 For :class:`int` operands, the three-argument form of ``pow`` now allows
   the second argument to be negative, permitting computation of modular
.. versionchanged:: 3.8
   Allow keyword arguments. Formerly, only positional arguments were
   supported.
```

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpythonain\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 1377)

Unknown directive type "function".

```
.. function:: print(*objects, sep=' ', end='\\n', file=sys.stdout, flush=False)
     Print *objects* to the text stream *file*, separated by *sep* and followed
                       *sep*, *end*, *file*, and *flush*, if present, must be given as keyword
    arguments.
    All non-keyword arguments are converted to strings like :func:`str` does and
    written to the stream, separated by *sep* and followed by *end*. Both *sep* and *end* must be strings; they can also be ``None``, which means to use the default values. If no *objects* are given, :func:`print` will just write
     *end*.
   The *file* argument must be an object with a ``write(string)`` method; if it is not present or ``None`', :data:`sys.stdout` will be used. Since printed arguments are converted to text strings, :func:`print` cannot be used with binary mode file objects. For these, use ``file.write(...)`` instead.
    Whether the output is buffered is usually determined by *file*, but if the *flush* keyword argument is true, the stream is forcibly flushed.
     .. versionchanged:: 3.3
         Added the *flush* keyword argument.
```

Return a property attribute.

fget is a function for getting an attribute value. fset is a function for setting an attribute value. fdel is a function for deleting an attribute value. And doc creates a docstring for the attribute.

A typical use is to define a managed attribute x:

```
class C:
   def __init__(se_
self._x = None
          _init__(self):
    def getx(self):
        return self. x
    def setx(self, value):
        self._x = value
    def delx(self):
        del self. x
    x = property(getx, setx, delx, "I'm the 'x' property.")
```

If c is an instance of C, c.x will invoke the getter, c.x = value will invoke the setter, and del c.x the deleter.

If given, doc will be the docstring of the property attribute. Otherwise, the property will copy fget's docstring (if it exists). This makes it possible to create read-only properties easily using :func:'property' as a :term' decorator':

 $System\,Message:\,ERROR/3\,(\text{D:}\colored ing-resources}) ample-onboarding-resources) courses and the colored ing-resources are considered in the colored index of the colored ind$ ain\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 1429); backlink Unknown interpreted text role "func".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 1429); backlink

Unknown interpreted text role "term".

```
class Parrot:
     def __init__(self):
    self._voltage = 100000
     def voltage(self):
    """Get the current voltage."""
           return self. voltage
```

The @property decorator turns the :meth: 'voltage' method into a "getter" for a read-only attribute with the same name, and it sets the docstring for voltage to "Get the current voltage."

.n\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 1442); backlink

Unknown interpreted text role "meth".

A property object has 'attr:'~property.getter', 'attr:'~property.setter', and 'attr:'~property.deleter' methods usable as decorators that

create a copy of the property with the corresponding accessor function set to the decorated function. This is best explained with an example:

 $System\ Message: ERROR/3\ (\texttt{D:\noboarding-resources}) sample-onboarding-resources \texttt{Cpython-main}\ (\texttt{Doc}\ (\texttt{library})\ functions.rst,\ line\ 1446);\ \textit{backlink}$

Unknown interpreted text role "attr".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main)\((Doc)\) (library) functions.rst, line 1446); backlink

Unknown interpreted text role "attr".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 1446); backlink

Unknown interpreted text role "attr".

```
class C:
    def __init__(self):
        self._x = None

    @property
    def x(self):
        """I'm the 'x' property."""
        return self._x

    @x.setter
    def x(self, value):
        self._x = value

    @x.deleter
    def x(self):
        del self. x
```

This code is exactly equivalent to the first example. Be sure to give the additional functions the same name as the original property (x in this case)

The returned property object also has the attributes fget, fset, and fdel corresponding to the constructor arguments.

```
.. function:: reversed(seq)
```

```
Return a reverse :term:`iterator`. *seq* must be an object which has a :meth:` reversed_` method or supports the sequence protocol (the :meth:` _len_` method and the :meth:` _getitem_` method with integer arguments starting at ``O``).
```

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 1507)

Unknown directive type "function".

.. function:: round(number[, ndigits])

Return *number* rounded to *ndigits* precision after the decimal point. If *ndigits* is omitted or is ``None``, it returns the nearest integer to its input.

For the built-in types supporting :func:`round`, values are rounded to the closest multiple of 10 to the power minus *ndigits*; if two multiples are equally close, rounding is done toward the even choice (so, for example, both ``round(0.5)`` and ``round(-0.5)`` are ``0``, and ``round(1.5)`` is ``2``). Any integer value is valid for *ndigits* (positive, zero, or negative). The return value is an integer if *ndigits* is omitted or ``None``.

Otherwise, the return value has the same type as *number*.

For a general Python object ``number``, ``round`` delegates to ``number. $_$ round $_$ ``.

.. note::

The behavior of :func:`round` for floats can be surprising: for example, ``round(2.675, 2)`` gives ``2.67`` instead of the expected ``2.68``. This is not a bug: it's a result of the fact that most decimal fractions can't be represented exactly as a float. See :ref:`tut-fp-issues` for more information.

Return a new xclass; set' object, optionally with elements taken from iterable. set is a built-in class. See xclass; set' and xref; typesset' for documentation about this class.

Unknown directive type "function".

```
.. function:: sorted(iterable, /, *, key=None, reverse=False)
```

Return a new sorted list from the items in *iterable*.

Has two optional arguments which must be specified as keyword arguments.

key specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, ``key=str.lower``). The default value is ``None`` (compare the elements directly).

reverse is a boolean value. If set to ``True``, then the list elements are sorted as if each comparison were reversed.

Use :func:`functools.cmp_to_key` to convert an old-style *cmp* function to a *key* function.

The built-in :func:`sorted` function is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal --- this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).

The sort algorithm uses only ``<` comparisons between items. While defining an :meth: `~object.__lt__` method will suffice for sorting, :PEP:`8` recommends that all six :ref:`rich comparisons <comparisons>` be implemented. This will help avoid bugs when using the same data with other ordering tools such as :func:`max` that rely on a different underlying method. Implementing all six comparisons also helps avoid confusion for mixed type comparisons which can call reflected the :meth: ~object.__gt__` method.

For sorting examples and a brief sorting tutorial, see :ref:`sortinghowto`.

 $System\ Message: ERROR/3\ (\texttt{D:\noboarding-resources}) sample-onboarding-resources \verb|\coc|| constant of the main of the main$

Unknown directive type "decorator".

```
.. decorator:: staticmethod
```

Transform a method into a static method.

A static method does not receive an implicit first argument. To declare a static method, use this idiom::

```
class C:
    @staticmethod
    def f(arg1, arg2, ...): ...
```

The ``@staticmethod`` form is a function :term:`decorator` -- see :ref:`function` for details.

A static method can be called either on the class (such as ``C.f()``) or on an instance (such as ``C().f()``). Moreover, they can be called as regular functions (such as ``f()``).

Static methods in Python are similar to those found in Java or C++. Also, see :func:`classmethod` for a variant that is useful for creating alternate class constructors.

Like all decorators, it is also possible to call ``staticmethod`` as a regular function and do something with its result. This is needed in some cases where you need a reference to a function from a class body and you want to avoid the automatic transformation to instance method. For these cases, use this idiom::

```
def regular_function():
    ...

class C:
    method = staticmethod(regular function)
```

For more information on static methods, see :ref:`types`.

```
.. versionchanged:: 3.10
Static methods now inherit the method attributes (``_module__`',
    ``_name__'', ``_qualname__'', ``_doc__'` and ``_annotations__''),
    have a new ``_wrapped__'` attribute, and are now callable as regular functions.
```

Unknown interpreted text role "func".

If the second argument is omitted, the super object returned is unbound. If the second argument is an object, isinstance(obj, type) must be true. If the second argument is a type, issubclass(type2, type) must be true (this is useful for classmethods).

There are two typical use cases for *super*. In a class hierarchy with single inheritance, *super* can be used to refer to parent classes without naming them explicitly, thus making the code more maintainable. This use closely parallels the use of *super* in other programming languages.

The second use case is to support cooperative multiple inheritance in a dynamic execution environment. This use case is unique to Python and is not found in statically compiled languages or languages that only support single inheritance. This makes it possible to implement "diamond diagrams" where multiple base classes implement the same method. Good design dictates that such implementations have the same calling signature in every case (because the order of calls is determined at runtime, because that order adapts to changes in the class hierarchy, and because that order can include sibling classes that are unknown prior to runtime).

For both use cases, a typical superclass call looks like this:

```
class C(B):
    def method(self, arg):
        super().method(arg)  # This does the same thing as:
        # super(C, self).method(arg)
```

In addition to method lookups, func: super also works for attribute lookups. One possible use case for this is calling term descriptors term descriptors <a

Unknown interpreted text role "term".

Note that :finc: super` is implemented as part of the binding process for explicit dotted attribute lookups such as super().__getitem__(name). It does so by implementing its own :meth'__getattribute__` method for searching classes in a predictable order that supports cooperative multiple inheritance. Accordingly, :finc: super` is undefined for implicit lookups using statements or operators such as super() [name].

Also note that, aside from the zero argument form, :func: super' is not limited to use inside methods. The two argument form specifies the arguments exactly and makes the appropriate references. The zero argument form only works inside a class definition, as the compiler fills in the necessary details to correctly retrieve the class being defined, as well as accessing the current instance for ordinary methods.

With three arguments, return a new type object. This is essentially a dynamic form of the <code>keyword:class</code> statement. The <code>name</code> string is the class name and becomes the <code>attr:~definition__name_</code> attribute. The <code>bases</code> tuple contains the base classes and becomes the <code>attr:~class__bases__</code> attribute; if empty, <code>class:object</code>, the ultimate base of all classes, is added. The <code>dict</code> dictionary contains attribute and method definitions for the class body; it may be copied or wrapped before becoming the <code>attr:~object__dict__</code> attribute. The following two statements create identical <code>class:type</code> objects:

Unknown directive type "versionchanged".

.. versionchanged:: 3.6
Subclasses of :class:`type` which don't override ``type.__new__`` may no longer use the one-argument form to get the type of an object.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 1799)

Unknown directive type "function".

```
.. function:: vars([object])

Return the :attr:`~object.__dict__` attribute for a module, class, instance, or any other object with a :attr:`~object.__dict__` attribute.
```

Objects such as modules and instances have an updateable :attr:`~object.__dict__` attribute; however, other objects may have write restrictions on their :attr:`~object.__dict__` attributes (for example, classes use a :class:`types.MappingProxyType` to prevent direct dictionary updates).

Without an argument, :func:`vars` acts like :func:`locals`. Note, the locals dictionary is only useful for reads since updates to the locals dictionary are ignored.

A :exc:`TypeError` exception is raised if an object is specified but it doesn't have a :attr:`~object.__dict__` attribute (for example, if its class defines the :attr:`~object.__slots__` attribute).

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 1817)

Unknown directive type "function".

```
.. function:: zip(*iterables, strict=False)
```

Iterate over several iterables in parallel, producing tuples with an item from each one.

Example::

```
>>> for item in zip([1, 2, 3], ['sugar', 'spice', 'everything nice']):
... print(item)
...
(1, 'sugar')
(2, 'spice')
(3, 'everything nice')
```

More formally: :func:`zip` returns an iterator of tuples, where the *i*-th tuple contains the *i*-th element from each of the argument iterables.

Another way to think of :func:`zip` is that it turns rows into columns, and columns into rows. This is similar to `transposing a matrix https://en.wikipedia.org/wiki/Transpose> .

:func:`zip` is lazy: The elements won't be processed until the iterable is iterated on, e.g. by a :keyword:`!for` loop or by wrapping in a :class:`list`.

One thing to consider is that the iterables passed to :func:`zip` could have different lengths; sometimes by design, and sometimes because of a bug in the code that prepared these iterables. Python offers three different approaches to dealing with this issue:

* By default, :func:`zip` stops when the shortest iterable is exhausted. It will ignore the remaining items in the longer iterables, cutting off the result to the length of the shortest iterable::

```
>>> list(zip(range(3), ['fee', 'fi', 'fo', 'fum']))
[(0, 'fee'), (1, 'fi'), (2, 'fo')]
```

* :func:`zip` is often used in cases where the iterables are assumed to be of equal length. In such cases, it's recommended to use the ``strict=True`` option. Its output is the same as regular :func:`zip`::

```
>>> list(zip(('a', 'b', 'c'), (1, 2, 3), strict=True))
```

```
[('a', 1), ('b', 2), ('c', 3)]
   Unlike the default behavior, it checks that the lengths of iterables are identical, raising a :exc:`ValueError` if they aren't:
         >>> list(zip(range(3), ['fee', 'fi', 'fo', 'fum'], strict=True))
        Traceback (most recent call last):
        ValueError: zip() argument 2 is longer than argument 1
   Without the ``strict=True`` argument, any bug that results in iterables of
   different lengths will be silenced, possibly manifesting as a hard-to-find bug in another part of the program.
^{\star} Shorter iterables can be padded with a constant value to make all the iterables have the same length. This is done by
   :func: `itertools.zip longest`.
Edge cases: With a single iterable argument, :func:`zip` returns an iterator of 1-tuples. With no arguments, it returns an empty iterator.
Tips and tricks:
 * The left-to-right evaluation order of the iterables is guaranteed. This
   The left-to-right evaluation order of the iterables is guaranteed. This makes possible an idiom for clustering a data series into n-length groups using ''zip(*[iter(s)]*n, strict=True)''. This repeats the *same* iterator ''n'' times so that each output tuple has the result of ''n'' calls to the iterator. This has the effect of dividing the input into n-length chunks.
* :func:`zip` in conjunction with the ``*`` operator can be used to unzip a
        >>> x = [1, 2, 3]
>>> y = [4, 5, 6]
        >>> y = [4, 3, 6]

>>> list(zip(x, y))

[(1, 4), (2, 5), (3, 6)]

>>> x2, y2 = zip(*zip(x, y))

>>> x == list(x2) and y == list(y2)
.. versionchanged:: 3.10
     Added the ``strict`` argument.
```

   ain\Doc\library\(cpython-main) (Doc) (library) functions.rst, line 1903)
        .. function:: __import__(name, globals=None, locals=None, fromlist=(), level=0)
               .. index::
                      statement: import
                     module: imp
               .. note::
                      This is an advanced function that is not needed in everyday Python
                      programming, unlike :func:`importlib.import_module`
               This function is invoked by the :keyword:`import` statement.
                                                                                                                                                                   It can be
               replaced (by importing the 'mod' builtins' module and assigning to 'builtins. import ') in order to change semantics of the
               ``builtins._import__``) in order to change semantics of the :keyword: '!import` statement, but doing so is **strongly** discouraged as it
              :keyword: !import statement, but during so is strong; discounting so is usually simpler to use import hooks (see :pep: 302') to attain the same goals and does not cause issues with code which assumes the default import implementation is in use. Direct use of :func:`_import__` is also
               discouraged in favor of :func: `importlib.import_module`.
               The function imports the module *name*, potentially using the given *globals*
               and *locals* to determine how to interpret the name in a package context. The *fromlist* gives the names of objects or submodules that should be
              imported from the module given by *name*. The standard implementation does not use its *locals* argument at all and uses its *globals* only to
              determine the package context of the :keyword: `import` statement.
               *level* specifies whether to use absolute or relative imports. ``O`` (the
              default) means only perform absolute imports. Positive values for *level* indicate the number of parent directories to search relative to the directory of the module calling :func:`_import__` (see :pep:`328` for the
              details).
              When the *name* variable is of the form ``package.module``, normally, the top-level package (the name up till the first dot) is returned, *not* the
              module named by *name*. However, when a non-empty *fromlist* argument is given, the module named by *name* is returned.
               For example, the statement ``import spam`` results in bytecode resembling the
               following code::
                      spam = __import__('spam', globals(), locals(), [], 0)
              The statement ``import spam.ham`` results in this call::
                                          import ('spam.ham', globals(), locals(), [], 0)
              Note how :func:`__import__` returns the toplevel module here because the object that is bound to a name by the :keyword:`import` statement.
                                                                              ` returns the toplevel module here because this is
               On the other hand, the statement ``from spam.ham import eggs, sausage as
               saus `` results in ::
                                              _import__('spam.ham', globals(), locals(), ['eggs', 'sausage'], 0)
                        temp =
                      _temp = __import__('
eggs = _temp.eggs
saus = _temp.sausage
               Here, the ``spam.ham`` module is returned from :func:`__import__`. From this
```

object, the names to import are retrieved and assigned to their respective ${\tt names}$

If you simply want to import a module (potentially within a package) by name, use :func: importlib.import_module $\dot{}$.

- .. versionchanged:: 3.3 $\,$ Negative values for *level* are no longer supported (which also changes the default value to 0).
- .. versionchanged:: 3.9
 When the command line options :option: `-E` or :option: `-I` are being used,
 the environment variable :envvar: `PYTHONCASEOK` is now ignored.
