# Yama

Yama is a Linux Security Module that collects system-wide DAC security protections that are not handled by the core kernel itself. This is selectable at build-time with <code>CONFIG\_SECURITY\_YAMA</code>, and can be controlled at run-time through sysctls in <code>/proc/sys/kernel/yama</code>:

## ptrace scope

As Linux grows in popularity, it will become a larger target for malware. One particularly troubling weakness of the Linux process interfaces is that a single user is able to examine the memory and running state of any of their processes. For example, if one application (e.g. Pidgin) was compromised, it would be possible for an attacker to attach to other running processes (e.g. Firefox, SSH sessions, GPG agent, etc) to extract additional credentials and continue to expand the scope of their attack without resorting to user-assisted phishing.

This is not a theoretical problem. SSH session hijacking and arbitrary code injection attacks already exist and remain possible if ptrace is allowed to operate as before. Since ptrace is not commonly used by non-developers and non-admins, system builders should be allowed the option to disable this debugging system.

For a solution, some applications use prct1 (PR\_SET\_DUMPABLE, ...) to specifically disallow such ptrace attachment (e.g. sshagent), but many do not. A more general solution is to only allow ptrace directly from a parent to a child process (i.e. direct "gdb EXE" and "strace EXE" still work), or with CAP SYS PTRACE (i.e. "gdb --pid=PID", and "strace -p PID" still work as root).

In mode 1, software that has defined application-specific relationships between a debugging process and its inferior (crash handlers, etc), prctl (PR\_SET\_PTRACER, pid, ...) can be used. An inferior can declare which other process (and its descendants) are allowed to call ptrace\_attach against it. Only one such declared debugging process can exists for each inferior at a time. For example, this is used by KDE, Chromium, and Firefox's crash handlers, and by Wine for allowing only Wine processes to ptrace each other. If a process wishes to entirely disable these ptrace restrictions, it can call prctl (PR\_SET\_PTRACER, PR\_SET\_PTRACER, ...) so that any otherwise allowed process (even those in external pid namespaces) may attach.

The sysctl settings (writable only with CAP SYS PTRACE) are:

#### 0 - classic ptrace permissions:

a process can PTRACE\_ATTACH to any other process running under the same uid, as long as it is dumpable (i.e. did not transition uids, start privileged, or have called <code>prctl(PR\_SET\_DUMPABLE...)</code> already). Similarly, <code>PTRACE\_TRACEME</code> is unchanged.

## 1 - restricted ptrace:

a process must have a predefined relationship with the inferior it wants to call PTRACE\_ATTACH on. By default, this relationship is that of only its descendants when the above classic criteria is also met. To change the relationship, an inferior can call PTRACE PTRACER, debugger, ...) to declare an allowed debugger PID to call PTRACE\_ATTACH on the inferior. Using PTRACE\_TRACEME is unchanged.

#### 2 - admin-only attach:

only processes with CAP\_SYS\_PTRACE may use ptrace, either with PTRACE\_ATTACH or through children calling PTRACE TRACEME.

### 3 - no attach:

no processes may use ptrace with PTRACE\_ATTACH nor via PTRACE\_TRACEME. Once set, this sysctl value cannot be changed.

The original children-only logic was based on the restrictions in grsecurity.
