What's New In Python 3.3

This article explains the new features in Python 3.3, compared to 3.2. Python 3.3 was released on September 29, 2012. For full details, see the changelog.

```
System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main] [Doc] [whatsnew] 3.3.rst, line 49)

Security improvements:

· Hash randomization is switched on by default.

Please read on for a comprehensive list of user-facing changes.

PEP 405: Virtual Environments

Virtual environments help create separate Python setups while sharing a system-wide base install, for ease of maintenance. Virtual environments have their own set of private site packages (i.e. locally-installed libraries), and are optionally segregated from the system-wide site packages. Their concept and implementation are inspired by the popular virtualenv third-party package, but benefit from tighter integration with the interpreter core.

This PEP adds the mod`verv` module for programmatic access, and the pyvenv script for command-line access and administration. The Python interpreter checks for a pyvenv.cfg, file whose existence signals the base of a virtual environment's directory tree.

PEP written by Carl Meyer; implementation by Carl Meyer and Vinay Sajip
```

PEP 420: Implicit Namespace Packages

Native support for package directories that don't require $_init_.py$ marker files and can automatically span multiple path segments (inspired by various third party approaches to namespace packages, as described in PEP 420)

PEP 3118: New memoryview implementation and buffer protocol documentation

The implementation of PEP 3118 has been significantly improved. $\label{eq:permutation}$

The new memoryview implementation comprehensively fixes all ownership and lifetime issues of dynamically allocated fields in the Py_{\perp} buffer struct that led to multiple crash reports. Additionally, several functions that crashed or returned incorrect results for non-contiguous or multi-dimensional input have been fixed.

The memoryview object now has a PEP-3118 compliant getbufferproc() that checks the consumer's request type. Many new features have been added, most of them work in full generality for non-contiguous arrays and arrays with suboffsets.

The documentation has been updated, clearly spelling out responsibilities for both exporters and consumers. Buffer request flags are grouped into basic and compound flags. The memory layout of non-contiguous and multi-dimensional NumPy-style arrays is explained.

Features

- All native single character format specifiers in struct module syntax (optionally prefixed with '@') are now supported.
- . With some restrictions, the cast() method allows changing of format and shape of C-contiguous arrays.
- Multi-dimensional list representations are supported for any array type.
- · Multi-dimensional comparisons are supported for any array type.
- One-dimensional memoryviews of hashable (read-only) types with formats B, b or c are now hashable. (Contributed by Antoine Pitrou in :issue: 13411'.)

 $System Message: ERROR/3 (p:\onboarding-resources\symple-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main\][Doc][whatsnew]3.3.rst, line 173); \\ backlink$

Unknown interpreted text role "issue".

 Arbitrary slicing of any 1-D arrays type is supported. For example, it is now possible to reverse a memoryview in O(1) by using a negative step.

API changes

- · The maximum number of dimensions is officially limited to 64.
- . The representation of empty shape, strides and suboffsets is now an empty tuple instead of None.
- Accessing a memoryview element with format 'B' (unsigned bytes) now returns an integer (in accordance with the struct module syntax). For returning a bytes object the view must be cast to 'c' first.
- memoryview comparisons now use the logical structure of the operands and compare all array elements by value. All format strings in struct module syntax are supported. Views with unrecognised format strings are still permitted, but will always compare as unequal, regardless of view contents.
- For further changes see Build and C API Changes and Porting C code.

(Contributed by Stefan Krah in :issue: 10181'.)

:pep: `3118` - Revising the Buffer Protocol
```

PEP 393: Flexible String Representation

The Unicode string type is changed to support multiple internal representations, depending on the character with the largest Unicode ordinal (1, 2, or 4 bytes) in the represented string. This allows a space-efficient representation in common cases, but gives access to full UCS-4 on all systems. For compatibility with existing APIs, several representations may exist in parallel; over time, this compatibility should be phased out.

On the Python side, there should be no downside to this change.

On the C API side, PEP 393 is fully backward compatible. The legacy API should remain available at least five years. Applications using the legacy API will not fully benefit of the memory reduction, or - worse - may use a bit more memory, because Python may have to maintain two versions of each string (in the legacy format and in the new efficient storage).

Functionality

Changes introduced by PEP 393 are the following:

- Python now always supports the full range of Unicode code points, including non-BMP ones (i.e. from u+0000 to u+10FFFF).
 The distinction between narrow and wide builds no longer exists and Python now behaves like a wide build, even under Windows.
- With the death of narrow builds, the problems specific to narrow builds have also been fixed, for example:
 - $\bullet \ \ \text{:finc:'len'} \ \, \text{now always returns 1 for non-BMP characters, so} \ \, \text{len}\left(\,'\, \setminus \texttt{U0010FFFF'}\,\right) \ \, == \ \, 1; \\$

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main] [Doc] [whatsnew] 3.3.rst, line 239); backlink
Unknown interpreted text role "func".

- surrogate pairs are not recombined in string literals, so '\uDBFF\uDFFF' != '\U0010FFFF':
- indexing or slicing non-BMP characters returns the expected value, so '\u0010FFFF' [0] now returns '\u0010FFFF' and not '\u0010FFFF';
- all other functions in the standard library now correctly handle non-BMP code points.
- The value of xdata'sys.maxunicode' is now always 1114111 (0x10FFFF in hexadecimal). The xcfine: PyUnicode_GetMax' function still returns either 0xFFFF or 0x10FFFF for backward compatibility, and it should not be used with the new Unicode API (see issue: 13054').

Performance and resource usage

The storage of Unicode strings now depends on the highest code point in the string:

- pure ASCII and Latin1 strings (U+0000-U+00FF) use 1 byte per code point;
- BMP strings (U+0000-U+FFFF) use 2 bytes per code point;
- non-BMP strings (U+10000-U+10FFFF) use 4 bytes per code point.

The net effect is that for most applications, memory usage of string storage should decrease significantly - especially compared to former wide unicode builds - as, in many cases, strings will be pure ASCII even in international contexts (because many strings store non-human language data, such as XML fragments, HTTP headers, JSON-encoded data, etc.). We also hope that it will, for the same reasons, increase CPU cache efficiency on non-trivial applications. The memory usage of Python 3.3 is two to three times smaller than Python 3.2, and a little bit better than Python 2.7, on a Django benchmark (see the PEP for details).

```

```

PEP 397: Python Launcher for Windows

The Python 3,3 Windows installer now includes a py launcher application that can be used to launch Python applications in a version independent fashion.

This launcher is invoked implicitly when double-clicking *.py files. If only a single Python version is installed on the system, that version will be used to run the file. If multiple versions are installed, the most recent version is used by default, but this can be overridden by including a Unix-style "shebang line" in the Python script.

The launcher can also be used explicitly from the command line as the py application. Running py follows the same version selection rules as implicitly launching scripts, but a more specific version can be selected by passing appropriate arguments (such as -3 to request Python 3 when Python 2 is also installed, or -2. 6 to specifically request an earlier Python version when a more recent version is installed).

In addition to the launcher, the Windows installer now includes an option to add the newly installed Python to the system PATH. (Contributed by Brian Curtin in :ssue: 3561'.)

```

PEP 3151: Reworking the OS and IO exception hierarchy

The hierarchy of exceptions raised by operating system errors is now both simplified and finer-grained.

You don't have to worry anymore about choosing the appropriate exception type between <code>exc:'OSError'</code>, <code>exc:'IOError'</code>, <code>exc:'EnvironmentError'</code>, <code>exc:'WindowsError'</code>, <code>exc:'mrap.error'</code>, <code>exc:'socket.error'</code> or <code>exc:'select.error'</code>. All these exception types are now only one: <code>exc:'OSError'</code>. The other names are kept as aliases for compatibility reasons.

```

```

PEP 380: Syntax for Delegating to a Subgenerator

PEP 380 adds the <code>yield from</code> expression, allowing a <code>term*</code> generator* to delegate part of its operations to another generator. This allows a section of code containing <code>keyword</code>: <code>yield</code> to be factored out and placed in another generator. Additionally, the subgenerator is allowed to return with a value, and the value is made available to the delegating generator.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main][Doc][whatsnew]3.3.rst, line 404); backlink

Unknown interpreted text role "term".

 $System\,Message:\,ERROR/3\,(\texttt{D:}\label{local_prop}) and in g-resources \verb|\sample-onboarding-resources| countries of the control of the contro$

```
main\Doc\whatsnew\[cpython-main][Doc][whatsnew]3.3.rst, line 404); backlink
```

Unknown interpreted text role "keyword".

While designed primarily for use in delegating to a subgenerator, the yield from expression actually allows delegation to arbitrary subjectors.

 $For simple \ iterators, \verb|yield from iterable| is essentially just a shortened form of \verb|for item| in iterable|: yield item|.$

```
>>> def g(x):
... yield from range(x, 0, -1)
... yield from range(x)
...
>>> list(g(5))
[5, 4, 3, 2, 1, 0, 1, 2, 3, 4]
```

However, unlike an ordinary loop, <code>yield from</code> allows subgenerators to receive sent and thrown values directly from the calling scope, and return a final value to the outer generator:

```
>>> def accumulate():
... tally = 0
... while 1:
... next = yield
... if next is None:
... return tally
... tally += next
...
>>> def gather tallies(tallies):
... while 1:
... tally = yield from accumulate()
... tallies.append(tally)
...
>>> tallies = []
>>> acc = gather_tallies(tallies)
>>> next(acc) # Ensure the accumulator is ready to accept values
>>> for i in range(4):
... acc.send(i)
...
>>> acc.send(None) # Finish the first tally
>>> tallies
>>> tallies
[6, 10]
```

The main principle driving this change is to allow even generators that are designed to be used with the <code>send</code> and <code>throw</code> methods to be split into multiple subgenerators as easily as a single large function can be split into multiple subfunctions.

PEP 409: Suppressing exception context

PEP 409 introduces new syntax that allows the display of the chained exception context to be disabled. This allows cleaner error messages in applications that convert between exception types:

Without the ${\tt from}$ None suffix to suppress the cause, the original exception would be displayed by default:

No debugging capability is lost, as the original exception context remains available if needed (for example, if an intervening library has incorrectly suppressed valuable underlying details):

```
>>> try:
... D({{}}).x
... except AttributeError as exc:
... print(repr(exc._context_))
...
```

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main][Doc][whatsnew]3.3.rst, line 525)

```

PEP 414: Explicit Unicode literals

 $To ease the transition from Python 2 for Unicode aware Python applications that make heavy \underline{\ \ } \ \ eof Unicode literals, Python 3.3$ once again supports the "u" prefix for string literals. This prefix has no semantic significance in Python 3, it is provided solely to reduce the number of purely mechanical changes in migrating to Python 3, making it easier for developers to focus on the more significant semantic changes (such as the stricter default separation of binary and text data).

```
System\ Message:\ ERROR/3\ (\texttt{D:} \verb|\conboarding-resources| sample-onboarding-resources| cpython-resources| constraints and the sample-onboarding-resources| constraints| constrai

                                                              :pep:`414` - Explicit Unicode literals
PEP written by Armin Ronacher.
```

PEP 3155: Qualified name for classes and functions

 $Functions \ and \ class \ objects \ have \ a \ new \ _qualname \ _ \ attribute \ representing \ the \ "path" \ from \ the \ module \ top-level \ to \ their \ definition.$ For global functions and classes, this is the same as __name__. For other functions and classes, it provides better information about where they were actually defined, and how they might be accessible from the global scope.

Example with (non-bound) methods:

```
>>> class C: ... def meth(self):
pass
>>> C.meth.__name_
'meth'
>>> C.meth.__qualname_
'C.meth'
```

Example with nested classes

```
>>> class C:
      class D:
def meth(self):
>>> C.D.__name__
>>> C.D._qualname__
    C.D.meth.__name__
/>> c....
'meth'
>>> C.D.meth.__qualname_
'C.D.meth'
```

Example with nested functions:

```
>>> def outer():
           def inner():
 pass
return inner
...
>>> outer().__name_
'inner'
>>> outer().__qualname__
'outer.<locals>.inner'
```

The string representation of those objects is also changed to include the new, more precise information:

```
>>> str(C.D)
"<class'_main_.C.D'>"
>>> str(C.D.meth)
'<function C.D.meth at 0x7f46b9fe31e0>'
```

```

PEP 412: Key-Sharing Dictionary

Dictionaries used for the storage of objects' attributes are now able to share part of their internal storage between each other (namely, the part which stores the keys and their respective hashes). This reduces the memory consumption of programs creating many instances of non-builtin types.

PEP 362: Function Signature Object

A new function :fine:'inspect.signature' makes introspection of python callables easy and straightforward. A broad range of callables is supported; python functions, decorated or not, classes, and func; functions, partial objects. New classes class; inspect. Signature', class; inspect. Parameter' and class; inspect. BoundArguments' hold information about the call signatures, such as, annotations, default values, parameters kinds, and bound arguments, which considerably simplifies writing decorators and any code that validates or amends calling signatures or arguments.

PEP 421: Adding sys.implementation

A new attribute on the mod'sys' module exposes details specific to the implementation of the currently running interpreter. The initial set of attributes on attr'sys implementation' are name, version, hexversion, and cache_tag.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main] [Doc] [whatsnew] 3.3.rst, line 648); backlink

Unknown interpreted text role "mod".

 $System Message: ERROR/3 (p:\onboarding-resources\ample-onboarding-resources\cpython-main\Doc\whatsnew\cite{Copython-main} [Doc] [whatsnew] 3.3.rst, line 648); backlink$

Unknown interpreted text role "attr".

The intention of sys.implementation is to consolidate into one namespace the implementation-specific data used by the standard library. This allows different Python implementations to share a single standard library code base much more easily. In its initial state, sys.implementation holds only a small portion of the implementation-specific data. Over time that ratio will shift in order to make the standard library more portable.

One example of improved standard library portability is <code>cache_tag</code>. As of Python 3.3, <code>sys.implementation.cache_tag</code> is used by <code>modimportlib</code> to support PEP 3147 compliance. Any Python implementation that uses <code>importlib</code> for its built-in import system may use <code>cache_tag</code> to control the caching behavior for modules.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main] [Doc] [whatsnew] 3.3.rst, line 660); backlink

Unknown interpreted text role "mod".

SimpleNamespace

The implementation of sys.implementation also introduces a new type to Python: class:types.SimpleNamespace. In contrast to a mapping-based namespace, like class:dict, simpleNamespace instances are writable. This means that you can add, remove, and modify the namespace through normal attribute access.

The :fine: import finction is now powered by :fine: import This work leads to the completion of "phase 2" of PEP 302. There are multiple benefits to this change. First, it has allowed for more of the machinery powering import to be exposed instead of being implicit and hidden within the C code. It also provides a single implementation for all Python VMs supporting Python 3.3 to use, helping to end any VM-specific deviations in import semantics. And finally it eases the maintenance of import, allowing for future growth to occur.

System Message: ERROR/3 (p:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main] [Doc] [whatsnew] 3.3.rst, line 691); backlink

For the common user, there should be no visible change in semantics. For those whose code currently manipulates import or calls import programmatically, the code changes that might possibly be required are covered in the Porting Python code section of this document.

New APIs

One of the large benefits of this work is the exposure of what goes into making the import statement work. That means the various importers that were once implicit are now fully exposed as part of the mod:importlib package.

Visible Changes

For potential required changes to code, see the Porting Python code section.

Beyond the expanse of what mode importile into expanse of what <a href="mode"/mortile"/move exposes, there are other visible changes to import. The biggest is that modes into expand hooks now store all of the meta path finders and path entry hooks used by import. Previously the finders were implicit and hidden within the C code of import instead of being directly exposed. This means that one can now easily remove or change the order of the various finders to fit one's needs.

Another change is that all modules have a __loader__ attribute, storing the loader used to create the module. PEP 302 has been updated to make this attribute mandatory for loaders to implement, so in the future once 3rd-party loaders have been updated people will be able to rely on the existence of the attribute. Until such time, though, import is setting the module post-load.

Loaders are also now expected to set the <code>_package_</code> attribute from PEP 366. Once again, import itself is already setting this on all loaders from <code>mod:importlib</code> and import itself is setting the attribute post-load.

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython main\Doc\whatsnew\[cpython-main] [Doc] [whatsnew] 3.3.rst, line 759); backlink

Unknown interpreted text role "mod".

None is now inserted into attr: sys.path_importer_cache` when no finder can be found on attr: sys.path_hooks`. Since cass: imp.NullImporter` is not directly exposed on attr: sys.path_hooks` it could no longer be relied upon to always be available to use as a value representing no finder found.

 $System Message: ERROR/3 \ (D:\onboarding-resources\ sample-onboarding-resources\ cpython main\ Doc\ whatsnew\ [cpython-main] \ [Doc] \ [whatsnew] 3.3.rst, line 763); \\ backlink$

A Finer-Grained Import Lock

Previous versions of CPython have always relied on a global import lock. This led to unexpected annoyances, such as deadlocks when importing a module would trigger code execution in a different thread as a side-effect. Clumsy workarounds were sometimes employed, such as the xifunc: "PyImport_ImportModuleNoBlock"> C API function.

System Message: ERROR/3 (p:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main] [Doc] [whatsnew] 3.3.rst, line 825); backlink
Unknown interpreted text role "cfine".

In Python 3.3, importing a module takes a per-module lock. This correctly serializes importation of a given module from multiple threads (preventing the exposure of incompletely initialized modules), while eliminating the aforementioned annoyances.

(Contributed by Antoine Pitrou in :issue: '9260'.)

New Modules

faulthandler

This new debug module mod: faulthandler' contains functions to dump Python tracebacks explicitly, on a fault (a crash like a segmentation fault), after a timeout, or on a user signal. Call func: faulthandler, enable' to install fault handlers for the <code>xonst: SIGSEGV', xonst: SIGHEFE', xonst: SIGBERT', xonst: SIGBUS', and xonst: SIGILL' signals. You can also enable them at startup by setting the <code>xenwar: PYTHONFAULTHANDLER</code>' environment variable or by using <code>xoption: -X'</code> faulthandler command line ontion.</code>

Unknown interpreted text role "issue".

C-module and libmpdec written by Stefan Krah.

The new C version of the decimal module integrates the high speed library for arbitrary precision correctly-rounded decimal floating point arithmetic. librapdec conforms to IBM's General Decimal Arithmetic Specification.

Performance gains range from 10x for database applications to 100x for numerically intensive applications. These numbers are expected gains for standard precisions used in decimal floating point arithmetic. Since the precision is user configurable, the exact figures may vary. For example, in integer bignum arithmetic the differences can be significantly higher.

The following table is meant as an illustration. Benchmarks are available at http://www.bytereef.org/mpdecimal/quickstart.html.

	decimal.py	_decimal	speedup
pi	42.02s	0.345s	120x
telco	172.19s	5.68s	30x
psycopg	3.57s	0.29s	12x

Features

• The :exc: `~decimal.FloatOperation` signal optionally enables stricter semantics for mixing floats and Decimals.

The <u>xbass</u>: <u>~decimal Decimal</u> constructor in decimal.py does not observe the context limits and converts values with arbitrary exponents or precision exactly. Since the C version has internal limits, the following scheme is used: If possible, values are converted exactly, otherwise <u>exec</u>: <u>~decimal.InvalidOperation</u> is raised and the result is NaN. In the latter case it is always possible to use <u>meth</u>: <u>~decimal.Context.create_decimal</u> in order to obtain a rounded or inexact value.

email

Policy Framework

The email package now has a mod:~email.policy' framework. A class:~email.policy.Policy' is an object with several methods and properties that control how the email package behaves. The primary policy for Python 3.3 is the class:~email.policy.Compat32 policy, which provides backward compatibility with the email package in Python 3.2. A policy can be specified when an email message is parsed by a mod:~email.parser', or when a class:~email.message.Message' object is created, or when an email is serialized using a mod:~email.generator'. Unless overridden, a policy passed to a parser is inherited by all the Message object and sub-objects created by the parser. By default a generator will use the policy of the Message object it is serializing. The default policy is data'.~email.policy.compat32'.

 $System Message: ERROR/3 (D:\onboarding-resources\ample-onboarding-resources\cpython-main\doc\whatsnew\cpython-main\doc\whatsnew\cpython-main\doc\docdording-resources\cpython-main\doc\docdording-resources\cpython-main\docdording-resources\cpyt$

The minimum set of controls implemented by all policy objects are:

System Message: ERROR/3 (b:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main] [Doc] [whatsnew] 3.3.rst, line 1212)

Unknown directive type "tabularcolumns".

.. tabularcolumns:: |1|L|

max_line_length	The maximum length, excluding the linesep character(s), individual lines may have when a Message is serialized. Defaults to 78.	
linesep	The character used to separate individual lines when a Message is serialized. Defaults to \n.	
cte_type	7bit or 8bit. 8bit applies only to a Bytes generator, and means that non-ASCII may be used where allowed by the protocol (or where it exists in the original input).	
raise_on_defect	Causes a parser to raise error when defects are encountered instead of adding them to the Message object's defects list.	

A new policy instance, with new settings, is created using the meth `~email_policy,Policy,clone` method of policy objects. clone takes any of the above controls as keyword arguments. Any control not specified in the call retains its default value. Thus you can create a policy that uses \r\n linesep characters like this:

 $System\ Message: ERROR/3\ (D:\onboarding-resources\sample-onboarding-resources\cpython-main\cp$

Unknown interpreted text role "meth".

mypolicy = compat32.clone(linesep='\r\n')

Policies can be used to make the generation of messages in the format needed by your application simpler. Instead of having to remember to specify linesep="\r\n'\n'\ in all the places you call a generator, you can specify it once, when you set the policy used by the parser or the Message, whichever your program uses to create Message objects. On the other hand, if you need to generate messages in multiple forms, you can still specify the parameters in the appropriate generator call. Or you can have custom policy instances for your different cases, and pass those in when you create the generator.

Provisional Policy with New Header API

While the policy framework is worthwhile all by itself, the main motivation for introducing it is to allow the creation of new policies that implement new features for the email package in a way that maintains backward compatibility for those who do not use the new policies. Because the new policies introduce a new API, we are releasing them in Python 3.3 as a term' provisional policy provisional package. Backwards incompatible changes (up to and including removal of the code) may occur if deemed necessary by the core developers.

header_factory

A callable that take a name and value and produces a custom header object.

The header_factory is the key to the new features provided by the new policies. When one of the new policies is used, any header retrieved from a Message object is an object produced by the header_factory, and any time you set a header on a Message it becomes an object produced by header_factory. All such header objects have a name attribute equal to the header name. Address and Date headers have additional attributes that give you access to the parsed data of the header. This means you can now do things like this:

```
>>> m = Message(policy=SMTP)
>>> m['To'] = 'Åkric <foo@example.com>'
>>> m['to']
'Åkric <foo@example.com>'
>>> m['to'].addresses
(Address(display_name='Åkric', username='foo', domain='example.com'),)
>>> m['to'].addresses[0].username
'foo'
>>> m['to'].addresses[0].display_name
'Åkric'
>>> m['Date'] = email.utils.localtime()
>>> m['Date'] = datetime (adatetime (2012, 5, 25, 21, 39, 24, 465484, tzinfo=datetime.timezone(datetime.timedelta(-1, 72000), 'EDT'))
>>> m['Date']
'Fri, 25 May 2012 21:44:27 -0400'
>>> print(m)
To: ='rutf-8?q?=C3=89ric?= <foo@example.com>
Date: Fri, 25 May 2012 21:44:27 -0400
```

You will note that the unicode display name is automatically encoded as utf-8 when the message is serialized, but that when the header is accessed directly, you get the unicode version. This eliminates any need to deal with the modi email.header meth email.header meth email.header functions.

System Message: ERROR/3 (p:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main] [Doc] [whatsnew] 3.3.rst, line 1309); backlink
Unknown interpreted text role "mod".

 $System Message: ERROR/3 (p:\onboarding-resources\ample-onboarding-resources\cpython-main\Doc\whatsnew\cite{Copython-main} [Doc] [whatsnew] 3.3.rst, line 1309); \\backlink$

Unknown interpreted text role "meth".

System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main][Doc][whatsnew]3.3.rst, line 1309); backlink

Unknown interpreted text role "meth".

You can also create addresses from parts:

```
>>> m['cc'] = [Group('pals', [Address('Bob', 'bob', 'example.com'),
... Address('Sally', 'sally', 'example.com')]),
... Address('Bonzo', addr_spec='bonz@laugh.com')]
>>> print(m)
To: = ?utf-8?q?=C3=89ric?= <foo@example.com>
Date: Fri, 25 May 2012 21:44:27 -0400
cc: pals: Bob <bod@example.com>, Sally <sally@example.com>;, Bonzo <bonz@laugh.com>
```

Decoding to unicode is done automatically:

```
>>> m2 = message_from_string(str(m))
>>> m2['to']
'Ã%ric <foo@example.com>'
```

When you parse a message, you can use the addresses and groups attributes of the header objects to access the groups and individual addresses:

```
>>> m2['cc'].addresses
(Address(display_name='Bob', username='bob', domain='example.com'), Address(display_name='Sally', username='sally', domain='example.com')
>>> m2['cc'].groups
(Group(display_name='pals', addresses=(Address(display_name='Bob', username='bob', domain='example.com'), Address(display_name='Sally', username='bob', domain='example.com'), Address(display_name='Sally', username='Dob', domain='example.com'), Address(display_name='Sally', username='Dob', domain='example.com'), Address(display_name='Sally', username='Sally', username='Sally', username='Dob', domain='example.com')
```

In summary, if you use one of the new policies, header manipulation works the way it ought to: your application works with unicode strings, and the email package transparently encodes and decodes the unicode to and from the RFC standard Content Transfer Encodings.

Other API Changes

New class: `~email.parser.BytesHeaderParser`, added to the mod: `~email.parser` module to complement class: `~email.parser.HeaderParser` and complete the Bytes API.

The mod'os' module has a new fine: ~os.sendfile' function which provides an efficient "zero-copy" way for copying data
from one file (or socket) descriptor to another. The phrase "zero-copy" refers to the fact that all of the copying of data
between the two descriptors is done entirely by the kernel, with no copying of data into userspace buffers. fine: ~os.sendfile
can be used to efficiently copy data from a file on disk to a network socket, e.g. for downloading a file.

Optimizations

Major performance enhancements have been added:

- Thanks to PEP 393, some operations on Unicode strings have been optimized:
 - o the memory footprint is divided by 2 to 4 depending on the text
 - encode an ASCII string to UTF-8 doesn't need to encode characters anymore, the UTF-8 representation is shared with the ASCII representation
 - o the UTF-8 encoder has been optimized
 - $\circ~$ repeating a single ASCII letter and getting a substring of an ASCII string is 4 times faster
- UTF-8 is now 2x to 4x faster. UTF-16 encoding is now up to 10x faster.

(Contributed by Serhiy Storchaka, issue: 14624', issue: 14738' and issue: 15026'.)

Deprecated

Unsupported Operating Systems

OS/2 and VMS are no longer supported due to the lack of a maintainer.

Windows 2000 and Windows platforms which set COMSPEC to command.com are no longer supported due to maintenance burden. OSF support, which was deprecated in 3.2, has been completely removed.

Deprecated Python modules, functions and methods

Passing a non-empty string to object.__format__() is deprecated, and will produce a .exc: TypeError in Python 3.4 (issue: 9856).

 $System Message: ERROR/3 (D:\onboarding-resources\sample-onboarding-resources\cpython-main\Doc\whatsnew\[cpython-main\][Doc][whatsnew] 3.3.rst, line 2225); \\ backlink$

Because None is now inserted into attr: sys.path_importer_cache*, if you are clearing out entries in the dictionary of paths that
do not have a finder, you will need to remove keys paired with values of None and x-lass: imp.NullImporter* to be
backwards-compatible. This will lead to extra overhead on older versions of Python that re-insert None into
attr: sys.path_importer_cache* where it represents the use of implicit finders, but semantically it should not change anything.

mod'pkgutil has been converted to use mod'importlib` internally. This eliminates many edge cases where the old behaviour
of the PEP 302 import emulation failed to match the behaviour of the real import system. The import emulation itself is still
present, but is now deprecated. The fine: pkgutil iter importers and fine: pkgutil walk packages functions special case the
standard import hooks so they are still supported even though they do not provide the non-standard iter_modules()
method.

• A longstanding RFC-compliance bug (issue: 1079') in the parsing done by fine: email header.decode_header' has been fixed. Code that uses the standard idiom to convert encoded headers into unicode (str(make_header(decode_header(h))) will see no change, but code that looks at the individual tuples returned by decode_header will see that whitespace that precedes or follows ASCII sections is now included in the ASCII section. Code that builds headers using make_header should also continue to work without change, since make_header continues to add whitespace between ASCII and non-ASCII sections if it is not already present in the input strings.

Code that used to work around the fact that the mod: threading' module used factory functions by subclassing the private
classes will need to change to subclass the now-public classes.

Unknown interpreted text role "mod".

The undocumented debugging machinery in the threading module has been removed, simplifying the code. This should have no
effect on production code, but is mentioned here in case any application debug frameworks were interacting with it
(issue: 13550').

Porting C code

In the course of changes to the buffer API the undocumented xmember: "Py_buffer.smalltable" member of the xtype: "Py_buffer' structure has been removed and the layout of the xtype: "PyMemoryViewObject" has changed.

All extensions relying on the relevant parts in memoryobject. h or object. h must be rebuilt.

 Due to ref: PEP 393 <pep-393>', the x:type: Py_UNICODE' type and all functions using this type are deprecated (but will stay available for at least five years). If you were using low-level Unicode APIs to construct and access unicode objects and you want to benefit of the memory footprint reduction provided by PEP 393, you have to convert your code to the new stoe: Unicode API <_/p>

Building C extensions

 The range of possible file names for C extensions has been narrowed. Very rarely used spellings have been suppressed: under POSIX, files named xxxmodule.so, xxxmodule.abi3.so and xxxmodule.cpython-*.so are no longer recognized as implementing the xxx module. If you had been generating such files, you have to switch to the other spellings (i.e., remove the module string from the file names).

(implemented in :issue:`14040`.)
