Meteor Guide

This is a setup to generate a static site from the markdown files location in `/source` using [Hexo](#).

Notes on Content Authoring

- In order for Hexo to pick up the title of a page, each markdown file should provide a `title` field using [YAML front matter](#). We can optionally include more meta information for each article, e.g. `authors`, if needed.

- Use **relative links** when linking to other pages in the guide. This is necessary because we are deploying multiple versions/branches of the site into nested folders.

Theme Development

```
git submodule update --init

npm install -g hexo-cli

npm install
# serve at localhost:4000
hexo server
```

The static site theme is `meteor`, loaded from an npm package, is responsible for the visual representation of the site. For more information, check out the [Hexo docs](#).

Continuous Deployment

- `devel` is automatically deployed as the production site via Netlify.

- Any branch that starts with `version-` will be automatically deployed in a sub-folder on every push. A branch with the name `version-1.2` will be deployed under the `v1.2` folder.

- To make a branch available in the site's version selection dropdown, make sure to add it to the `versions` list in `_config.yaml`!

- Pull Requests will generate deploy previews.

- All other branches are ignored.

Manual Deployment

In the `site` directory:

1. Create `keys.json` (search for "guide_push" in LastPass):

```
{
  "key": "xxx",
  "secret": "xxx"
}
```

2. `node deploy` .
