reload

Source code of released version | Source code of development version ***

The `reload` package handles the process of *migrating* an app: serializing the app's state, then shutting down and restarting the app (for example, to load updated client code or to move the client session from one JavaScript virtual machine to another), and finally restoring its state.

Packages that want to participate in the migration process register with `reload`. They can make the migration process wait until they are ready and include whatever state they may possess in the serialization and deserialization process.

`reload` is part of the Webapp project.
