mongo-dev-server

When the `mongo-dev-server` package is included in a Meteor application, a local development MongoDB server is started alongside the application. This package is mostly used internally, as it is included by default with any application that has a dependency on `mongo` (which is most Meteor applications). In some cases however, people might be interested in using the Meteor Tool without having to start a local development Mongo instance (e.g. when using Meteor as a build system). If an application has no dependency on `mongo`, the `mongo-dev-server` package will be removed (since it is a direct dependency of the `mongo` package), and no local development Mongo server will be started.

Note this is a `debugOnly` package, meaning it will not be included in any production bundles.
