There are multiple ways to create routes in Gatsby.

Creating individual pages

The simplest way to create a page is to export a React component from a page located in the `src/pages` directory. For example, exporting a component from `src/pages/about.js` will create a route at `/about`. More details in the [Routing Reference](#)

Collection Routing

Gatsby supports multiple templated pages based on a single component. For example, a file located at `src/pages/products/{Product.name}.js` can generate pages like `/products/burger`, based on information coming in from a CMS or other data source. For details, look at the [File System Route API](#) documentation.

Creating pages from Markdown

In order to enable a better content composition experience, Gatsby allows you to create both individual pages and dynamic routes using either [Markdown files](#) or [MDX files](#).

Using gatsby-node.js

If you need more fine-grained control over routing, you can programmatically create pages in `gatsby-node.js`. More details in the [Routing Reference](#)

Dynamic and Authenticated routing

For pages dealing with sensitive information, Gatsby lets you create [client-only routes](#) that live behind an authentication gate.
